Printing History

New editions are complete revisions of the manual. Update packages (formerly known as "Manual Changes") are issued between editions. They contain additional and replacement pages to be merged into the manual by the customer. The dates on the title page change only when a new edition or a new update is published. No information is incorporated into a reprinting unless it appears as a prior update. The edition does not change when an update is incorporated.

Many product updates and fixes do not require manual changes and, conversely, manual corrections may be done without accompanying product changes. Therefore, do not expect a one-to-one correlation between product updates and manual updates.

Edition 1 .... February 1989

Computer Museum

1 Programming Conventions

Introduction

This manual describes the DataCommC functions included in the DataCommC libraries. It assumes that you are familiar with the C language and with the DataCommC Development and Run-time Environments. If you have questions about editing, compiling, linking or running a program, see *The DataCommC Programming Language User's Guide*. If you have a question about the C language, see *The C Programming Language* by Kernighan and Ritchie, which is included in the documentation package.

Path and File Names

Some of the functions in the DataCommC library expect to receive strings representing path and file names as input arguments. These functions break the path/file name string into its individual components (drive:directory/filename.extension) and then pass the components to the HP 4954A Protocol Analyzer's operating system. The operating system controls the directory/file structure of the protocol analyzer's disc system.

Case Sensitivity

Both the DataCommC Programming Language and the protocol analyzer operating system use case sensitive file names. The following three file names identify three different files:

```
FILE1.csource
file1.csource
File1.csource
```

File Extensions

In general, all references to file names must use the file's complete extension name. The include files used with the examples in this manual are all shown as `.include` files; however, they could have been entered with `.h` extensions. This is one of the two cases in which the full DataCommC file extension does not need to be used. In the DataCommC environment:

this extension is equivalent to	this one.
.include	.h
.csource	.c

See *The DataCommC Programming Language User's Guide* for more information about the other DataCommC file extensions.

Viewing Program Results

After a DataCommC program has finished executing, control is passed back to the DataCommC environment, and any information the program placed on the display is lost as it is overwritten by the Run Program Menu. This can be avoided if the last routine in the program is an endless loop (for example, `while(1);`) or a wait-for-input (`getch();`) function. Pause functions also work, but are a little more difficult to implement.

Here is a sample program showing the wait-for-input function at the end:

```
main()
{
    printf("Hello, world",\n);

    getch();
}
```

In this case, the text `Hello, world`, remains on the display until a key is pressed on the keyboard. If `getch()` is replaced with `while(1)`, the program waits until the Reset key is pressed before terminating.

2

Library Overview

Character Classification and Conversion

isalnum( )	Tests for alphanumeric character.
isalpha( )	Tests for alphabetic character.
isascii( )	Tests for ascii character.
iscntrl( )	Tests for control character.
isdigit( )	Tests for decimal digit.
isgraph( )	Tests for printable/whitespace character.
islower( )	Tests for lowercase character.
isprint( )	Tests for printable character.
ispunct( )	Tests for punctuation character.
isspace( )	Tests for whitespace character.
isupper( )	Tests for uppercase character.
isxdigit( )	Tests for hex digit.
toascii( )	Converts a character to ascii.
tolower( )	Converts character to lowercase (if possible).
toupper( )	Converts character to uppercase (if possible).

Data Control

get_data_source( ) Gets the current data source and data files values.

resend_bops( ) Retransmits the last bit-oriented protocol string sent on the line.

sendf( ) Sends a formatted string to the line.

set_buffer_sizes( ) Sets the sizes for the primary DTE and DCE data buffers.

set_data_source( ) Allows a program to set either the line or a disc file as the source for the data buffer input.

start_data( ) Activates the data link control hardware and starts data acquisition.

stop_data( ) Halts the data link control hardware and stops data acquisition.

wait_data( ) Gets the first message of type DATACOMM.

Directory Control

ch_dir( ) Sets the current directory.

get_dir( ) Gets the current directory.

makedir( ) Creates a string representing a directory path.

parsedir( ) Breaks the given directory path into its components.

HP Computer Museum
www.hpmuseum.net

For research and education purposes only.

Display

center( )	Writes a string centered on the display.
cursor_off( )	Makes the cursor invisible.
cursor_on( )	Makes the cursor visible.
get_attribute( )	Returns the value of the current screen attribute.
get_cursor( )	Returns the current row and column position of the cursor.
put_all_sks( )	Writes the given labels onto the corresponding softkeys.
put_sk( )	Writes a label onto one of the eight softkeys.
putch( )	Writes a character to the display at the current cursor position.
puts( )	Writes a string to the display.
read_vidram( )	Reads the video RAM character and attribute value at the current cursor location.
restore_cursor( )	Restores the cursor to the display position.
roll_down( )	Rolls lines of text toward the bottom of the display.
roll_up( )	Rolls lines of text toward the top of the display.
save_cursor( )	Saves the current position of the cursor.
set_attribute( )	Sets the value of the current display attribute.
set_cursor( )	Places the cursor on the row and column indicated.
set_disp_bank( )	Selects one of the four graphics character display banks.
set_rows( )	Defines a text window on the display.

set_screen_mode()	Sets the screen mode to normal or tranparent text mode.
sys_msg()	Writes the given string to the display.
wipe()	Clears the display.
write_vidram()	Writes a character and its attribute to the video RAM location.

Events

get_event_bounds()	Gets pointers to the event buffer's first and last events.
hold_event()	Retains access to the event specified.
release_event()	Releases access to a specified event in the event buffer.

File Manipulation

close()	Closes a file opened by the open function.
eq_file_time()	Compares two files to determine which was modified more recently.
fclose()	Closes a file opened by the fopen function.
fflush()	Flushes the buffer associated with a file.
fgetc()	Gets a character from the specified file.
fgets()	Gets a string from the specified file.
file_time()	Returns the time when the specified file was last modified.
fopen()	Opens a file and returns a pointer to the file.
fprintf()	Prints formatted information into the specified file.

fputc( )	Adds a character to the specified file.
fputs( )	Puts a string into the specified file.
fread( )	Reads an array from the specified file.
fscanf( )	Reads formatted information from the specified file.
fseek( )	Moves the file pointer to a specified location in the file.
fwrite( )	Writes an array to a file or output string.
lseek( )	Moves the file pointer to a specified location in the file.
make_file( )	Creates a file.
open( )	Opens a file.
putc( )	Writes a character to a file or an output stream.
putchar( )	Writes a character to the standard output stream.
read( )	Reads from a file.
ungetc( )	Pushes a character back onto the input stream.
ungetch( )	Pushes a keystroke back into the system queue.
unlink( )	Deletes a file.
write( )	Writes to a file.

Formatting

atof( )	Converts a string of characters to the double number it represents.
atoi( )	Converts a string of characters to an integer representation.
atol( )	Converts a string of characters to a long integer representation.
ftoa( )	Converts a floating-point or double precision number to an ASCII character string.
itoa( )	Converts an integer to a null-terminated character string.
ltoa( )	Converts a long integer to a null-terminated character string.
printf( )	Outputs arguments to the standard output device.
scanf( )	Reads formatted information from the standard input stream.
sprintf( )	Outputs or prints argument string in memory.
sscanf( )	Reads formatted information from the specified buffer or string.

Front-End Control

get_bitrate( )	Gets the current bitrate value.
get_channelconfig( )	Gets the current configuration for a given channel.
get_datacode( )	Gets the currently selected datacode value.
get_duplex( )	Gets the current duplex value (either half- or full-duplex).
get_errorcheck( )	Getsthe currently selected error check value.
get_mode( )	Gets the currently selected synchronization mode.

get_parity( )	Gets the currently selected parity value.
get_protocol( )	Gets the currently selected protocol value.
get_resyncafter( )	Gets the currently selected resyncafter value.
get_resynchars( )	Gets the values of the currently selected resync characters.
get_resyncmode( )	Gets the currently selected resync mode value.
get_startbcc( )	Gets the currently selected startbcc characters.
get_stopbcc( )	Gets the currently selected stopbcc characters.
get_synchars( )	Gets the values of currently selected sync characters.
get_transtext( )	Gets the value of currently selected transparent text character.
resync( )	Manually reestablishes sync on the line.
set_bcc( )	Sets the protocol rules for calculating the block check character.
set_bitrate( )	Sets the bitrate.
set_channelconfig( )	Sets the configuration of the specified channel.
set_duplex( )	Modifies the duplex value.
set_protocol( )	Sets the protocol, mode, datacode, errorcheck and parity values.
set_resync( )	Defines protocol rules for resynching.
set_sync( )	Sets the values of the sync characters and synchronization mode.
set_transtext( )	Defines the protocol rules for transparent text mode.

Keyboard

getc( )	Reads a character from a file.
getch( )	Reads an unbuffered character from the keyboard.
getchar( )	Reads a character from stdin, the standard input stream.
gets( )	Reads a character string from the standard input stream.
is_key_avail( )	Checks the keyboard buffer for available keys.
keyboard_lock( )	Locks the keyboard for exclusive use by the current process.
keyboard_unlock	Unlocks keyboard and allows another process to take control of keyboard.

Lead and Pod Control

get_ignored_leads( )	Gets the currently selected ignored lead values.
get_lead( )	Verifies the state of the lead at the top of the incoming message queue.
get_lead_control( )	Gets the current lead control value.
get_stop_states( )	Gets the current stop state for the specified lead.
read_pod_id( )	Reads the pod identification.
reset_pod( )	Resets the attached pod.
set_ignored_leads( )	Sets the ignored leads for the attached pod.
set_lead( )	Sets a lead to the state specified.
set_lead_control( )	Modifies the lead control value.

set_stop_states( ) Sets the stop states of the specified interface lead.

wait_lead( ) Scans the message queue and collects the first message of type DATACOMM.

Math

abs( ) Calculates the absolute value of a value.

acos( ) Calculates the arccosine of a value.

asin( ) Calculates the arcsine of a value.

atan( ) Calculates the arctangent of a value.

atan2( ) Calculates the arctangent when two values are supplied.

ceil( ) Returns the next largest integer.

cos( ) Calculates the cosine of a value.

cosh( ) Calculates the hyperbolic cosine of a value.

cotan( ) Calculates the cotangent of a value.

exp( ) Calculates the exponential function.

fabs( ) Calculates the absolute value for a floating-point number.

floor( ) Returns the next smallest integer.

log( ) Calculates the natural log.

log10( ) Calculates the base 10 log.

pow( ) Calculates a value raised to a power.

rand( ) Returns a positive pseudo-random number between 0 and 32767.

sin( )	Calculates the sine of a value.
sinh( )	Calculates the hyperbolic sine of a value.
sqrt( )	Calculates the square root.
srand( )	Sets the seed of the random-number generator.
tan( )	Calculates the tangent of a value.
tanh( )	Calculates the hyperbolic tangent of a value.

Memory Allocation

calloc( )	Allocates a specified amount of zeroed storage.
free( )	Returns storage to the heap.
malloc( )	Allocates a specified amount of storage.

Messages and Error Handling

error_notification( )	Sends an error message to the error message queue.
init_trigger( )	Initializes the system trigger function.
is_msg_avail( )	Polls the process message queue for an available message.
read_message( )	Reads a message from the message queue.
send_message( )	Sends a message to the specified message queue.
set_error_handler( )	Designates an error message queue.
trigger_on_message( )	Returns when a message set up as a trigger is found..

Miscellaneous

assert( )	Macro used in identifying logic errors.
beep( )	Produces an audible alarm.
longjmp( )	Restores stack environment values.
setjmp( )	Saves the stack environment values.

Port

init_rs232( )	Initializes the serial port.
print_char( )	Prints a character through the RS232 port.
read_rs232( )	Reads a character from the serial port.
rs232_lock( )	Locks the RS232 port for exclusive use by the calling process.
rs232_read_ready	Checks the status of the RS232 receive register.
rs232_unlock	Releases control of the RS232 port.
rs232_write_ready	Checks the status of the RS232 transmit register.
write_rs232( )	Writes a character to the serial port.

Process Control

exit( )	Closes files and exits a process.
spawn( )	Creates a process that can execute independently of the calling process.
spawnw( )	Creates an independent process; the calling process is blocked until the new process terminates.

Real-Time Clock

get_time( )	Captures the current system time from the real-time clock.
set_time( )	Sets the current system time.

Run-Time Display

display_keys_on( )	Sends a message to the Run-time Display process telling to put it in the keyboard-on state.
examine_data( )	Allows the DataCommC examine data process to be spawned programmatically.
start_display( )	Initializes and spawns a Run-time Display or decode process.
stop_display( )	Terminates execution of the active Run-time Display process.

String Manipulation

bufcpy( )	Copies the contents of memory from one location to another.
clearn( )	Clears a specified amount of storage space.
filln( )	Fills a specified amount of storage space with a given character.
strcat( )	Appends (concatenates) one string to the end of another string.
strchr( )	Returns the position of a character in a string.
strcmp( )	Compares two strings.
strcmpl( )	Compares two strings, but ignores case differences.
strcpy( )	Copies one string to another.
strlen( )	Finds the length of a string.
strncat( )	Appends (concatenates) a specified number of characters from one string onto the end of another string.
strncmp( )	Compares a specified number of characters of one string to another string.
strncpy( )	Copies a specified number of characters from one string to another string.
strrchr( )	Returns a pointer to the last occurrence of a character in string.
strsave( )	Returns a pointer to the new copy of the string.
strtrm( )	Trims trailing spaces from a string.

Timing Services

clear_timer( )	Cancels a timer.
set_timer( )	Sets one of the DataCommC timers for the duration specified.
wait( )	Pauses for a given amount of time.

3

Library Functions

This chapter is an alphabetical list of the functions provided with the HP 18320A DataCommC Programming Language. For a list of these functions grouped by operational category, see chapter 2 of this manual, "Library Overview." For more information about the contents of the supplied include files, refer to chapter 4, "Include Files."

In this chapter, each function is described using the following format:

Format: A program fragment showing the function's declaration type, and the position and declaration types of its parameters, if any. The fragment also lists any necessary include files. If the functions' return values may be represented by the constant values in the `retval.include` file, that file is also listed.

Description: A description of what the function does, including a list of the acceptable values that may be used for input parameters and the possible values returned by output parameters.

Return Values: A list of the values that the function may return, and short descriptions of the conditions that could cause those values to be returned.

See Also: Other related functions in the DataCommC Library.

Example: A short program showing how the function is used.

Note The examples in this section are provided for clarification only. HP assumes no responsibility for their functionality or fitness for a specific purpose.

---

abs( )

Format:

```
int abs(num)
int num;
```

Description:

Calculates the absolute value of an integer (num).

Return Values:

Returns the absolute value of num.

See Also:

```
fabs()
```

Example:

```
main()
{
    int num1 = -8, num2;
    num2 = abs(num1);
    printf("The absolute value of %d is %d",num1, num2);
    getch();
}
```

acos( )

Format:

```
#include <math.include>

double acos(x)
double x;
```

Description:

Calculates the arccosine of x where x is a radian value between -1 and 1.

Return Values:

Returns the arccosine of x (in the range 0 to pi).

See Also:

```
asin(), atan(), atan2(), cos(), cosh(), cotan(), sin(), sinh(), tan(), tanh()
```

Example:

```
#include <math.include>
#define PI 3.141592654

main()
{
   double radx, degx, x=0.5;

   radx = acos(x);
   degx = radx * 180 / PI;        /* convert to degrees */
   printf("The arccosine of %f is %f degrees, or %f in radians.", x, degx, radx);
   getch();
}
```

asin( )

Format:

```
#include <math.include>

double asin(x)
double x;
```

Description:

Calculates the arcsine of x where x is a radian value between -1 and 1.

Return Values:

Returns the arcsine of x (in the range -pi/2 to pi/2).

See Also:

```
acos(), atan(), atan2(), cos(), cosh(), cotan(), sin(), sinh(), tan(), tanh()
```

Example:

```
#include <math.include>
#define PI 3.141592654

main()
{
    double radx, degx, x=0.5;

    radx = asin(x);
    degx = radx * 180 / PI;        /* convert to degrees */
    printf("The arcsine of %f is %f (degrees), or %f (in radians)", x, degx, radx);
    getch();
}
```

assert( )

Format:

```
#include <assert.include>

assert(expr)
int expr;
```

Description:

assert() is a macro useful for identifying logic errors when strategically placed in a program. As the program executes, the assert expression, expr, is evaluated, and if the integer result is FALSE (zero), a diagnostic message is printed:

```
Assertion failed: expr, file ffff.csource, line lnnn
```

where ffff is the name of the source file, including the path, and nnn is the line number of the assert statement that failed. The macro then calls error_notification() to place an error message on the screen along with softkeys that may be used to choose whether or not program execution continues.

The assert.include file defines this macro, and must be included in each program that uses assert(). When the assert statement is no longer needed, place the directive #define NDEBUG before the #include <assert.include> directive, and assert functions are excluded from the source file created by the preprocessor.

See Also:

error_notification()

assert( )

Example:

```
#include <assert.include>

main()
{
    char ch;

    ch = getch();
    assert(ch >= '0' && ch <= '9');
    printf("The result is %c\n", ch);

    getch();
}
```

atan( ), atan2( )

Format:

```
#include <math.include>

double atan(x)
double x;

double atan2(x,y)
double x,y;
```

Description:

The atan function calculates the arctangent of x where x is a radian value between -1 and 1.

The atan2 function calculates the arctangent of x/y where x and y are each radian values between -1 and 1 (x and y may be given opposite signs).

Return Values:

The atan function returns the arctangent result in the range -pi/2 to pi/2. The atan2 function returns the arctangent result in the range -pi to pi.

See Also:

```
acos(), asin(), cos(), cosh(), cotan(), sin(), sinh(), tan(), tanh()
```

atan( ), atan2( )

Example:

```
#include <math.include>
#define PI 3.141592654

main()
{

    double radx, degx, x=0.5;

    radx = atan(x);
    degx = radx * 180 / PI;       /* convert to degrees */
    printf("The arctangent of %f is %f (degrees), or %f (in radians)", x, degx, radx);
    getch();
}
```

atof( )

Format:

```
#include <stdlib.include>

double atof(str)
char *str;
```

Description:

The `atof` function converts a string of characters to the double number that it represents. `atof()` recognizes a string of numeric characters that may (but is not required to) contain a decimal point. If desired, the numerals may be preceded by blanks and tabs (which are ignored) and/or an optional sign, and followed by an `e` or `E` character with an optionally signed integer. For example, this string is valid:

```
"   895.9e-2"
```

Return Values:

Returns the result of the conversion, or, if `str` points to an unrecognizable or non-existent string, zero is returned.

See also:

`atoi(), atol(), ftoa()`

atof( )

Example:

```
#include <stdlib.include>

main()
{
    char *str;
    double result;

    str = "  104.543e5";       /* test leading blanks and positive exponent */
    result = atof(str);
    printf("%s was converted to %f\n\n", str, result);
    getch();
}
```

Library Functions

atoi( )

Format:

```
#include <stdlib.include>

int atoi(str)
char *str;
```

Description:

Converts a string of characters to an integer representation. Recognizes a string containing leading blanks and tabs (which are ignored), an optional sign, then a string of digits.

Return Values:

Returns the result of the conversion, or zero if `str` points to an unrecognizable or non-existent string.

See Also:

```
atof(), atol(), ftoa()
```

Library Functions

atoi( )

Example:

```
#include <stdlib.include>

main()
{

    char *str;
    int result;

    str = "  104";      /* test leading blanks */
    result = atoi(str);

    printf("%s was converted to %d\n\n", str, result);
    getch();
}
```

atol( )

Format:

```
#include <stdlib.include>

long atol(str)
char *str;
```

Description:

Converts a string of characters to a long integer representation. The function expects to receive a string containing optional leading blanks and tabs (which are ignored), an optional sign, then a string of digits.

Return Values:

Returns the result of the conversion, or zero if `str` points to an unrecognizable or non-existent string.

See Also:

```
atof(), atoi(), ftoa()
```

atol( )

Example:

```
#include <stdlib.include>

main()
{

    char *str;
    long result;

    str = "  104500";
    result = atol(str);

    printf("%s was converted to %ld\n\n", str, result);
    getch();
}
```

Library Functions

beep( )

Format:

```
void beep()
```

Description:

Causes the protocol analyzer to generate an audible alarm for 1/2 second.

Return Values:

None

Example:

```
main()
{
    beep();
}
```

bufcpy( )

Format:

```
void bufcpy(dest, source, n)
char *dest;
char *source;
int n;
```

Description:

Copies n bytes from source to dest, regardless of any control characters.

Return Values:

None

Example:

```
main()
{

    char *source;
    char dest[80];

    source = "hello world";
    bufcpy(dest,source,strlen(source));
    dest[strlen(source)] = 0;
    printf("The buffer copied is \"%s\".",dest);
    getch();
}
```

calloc( )

Format:

```
#include <stdlib.include>

char *calloc(num, size)
unsigned int num;
unsigned int size;
```

Description:

Allocates num contiguous units (blocks) of zeroed memory of size bytes each. The total size of the allocated block (num multiplied by size) cannot exceed 32K bytes. When memory allocated in this way is no longer being used, it should be returned to the system by calling free().

Return Values:

Returns pointer to the allocated memory, or NULL if the operation fails.

See Also:

```
free(), malloc()
```

calloc( )

Example:

```
#include <stdlib.include>

main()
{
   char *str, *new_str;

   str="hello world";
   if(new_str=calloc(1,strlen(str) + 1)) /* add 1 to the length for the NULL char. */
   {
      strcpy(new_str,str);
      printf("The new_str is %s.",new_str);
   }
   else
      printf("Memory could not be allocated");
   getch();
}
```

Library Functions

ceil( )

Format:

```
#include <math.include>

double ceil(x);
double x;
```

Description

Calculates the value (in `double` representation) of the next integer larger than `x`.

Return Values:

Returns the value of the next largest integer.

Example:

```
#include <math.include>

main()
{
    double x = 1.25;
    double x1;

    x1 = ceil(x);
    printf("ceil(%f) is %f.", x, x1);
    getch();
}
```

Library Functions

center( )

Format:

```
void center(string,row)
char *string;
int row;
```

Description:

This function writes a string to the display (padded on either side with spaces to center it) with the current display attributes. This takes the whole row.

The cursor position is moved to row `row`, column 1.

If the row is specified out of range (that is, larger than 25), no action is taken and the cursor is not moved. Similarly, no action is taken if string is `NULL`. If `string` is empty ("") the row is filled with spaces.

Return Values:

None

Example:

```
main()
{

   center("This message is centered on line 10.", 10);
   getch();
}
```

ch_dir()

Format:

```
void ch_dir(path)
char *path;
```

Description:

Sets the current global directory.

Return Values:

None

See Also:

```
get_dir(), makedir(), parsedir()
```

Example:

```
main()
{
    char new_path[81];

    ch_dir("c:C");

    get_dir(new_path);
    printf("The current default path is %s.",new_path);
    getch();
}
```

clear_timer( )

Format:

```
int clear_timer(timer_number)
int timer_number;
```

Description:

Cancels a timer, using `timer_number` to identify the selected timer.

Return Values:

Returns the number of the cancelled timer when successful, or

-1 if the timer number does not correspond to an active timer; the request is ignored.

See Also:

`set_timer()`

Example:

```
main()
{
    int timer,cleared_timer;

    if((timer = set_timer(5L)) == -1)         /* set the timer for 1/2 second */
        printf("Timer could not be set.");

    else
    {
        printf("timer %d set.\n",timer);
        if((cleared_timer = clear_timer(timer)) != -1) /* try to clear it */
            printf("Timer %d cleared.",cleared_timer);

        else
            printf("Timer %d could not be cleared.",timer);
    }
    getch();
}
```

clearn( )

Format:

```
void clearn(n, ptr)
int n;
char *ptr;
```

Description:

Clears n bytes beginning at ptr.

Return Values:

None

Example:

```
main()
{
    char *str;

    str = "Hello World";

    printf("The string before the clearn() call is %s.",str);
    clearn(strlen(str) + 1,str);
    printf("The string after the clearn() call is %s.",str);
    getch();
}
```

close( )

Format:

```
#include <fcntl.include>

int close(file_desc)
int file_desc;
```

Description:

Closes a file opened by the open function.

Return Values:

0	The close operation was successful.
-1	An error occurred during the close operation.

See Also:

open( )

close( )

Example:

```
#include <fcntl.include>

main()
{

    int fdesc;

    if ((fdesc = open("c:TEMP",O_WRONLY)) == -1)
       printf("Error in file opening!");

    else
       close(fdesc);
    getch();
}
```

Library Functions

cos( )

Format:

```
#include <math.include>

double cos(x)
double x;
```

Description:

Calculates the cosine of x.

Return Values:

Returns the cosine of x (a value between 1 and -1).

See Also:

```
acos(), asin(), atan(), atan2(), cosh(), cotan(), sin(), sinh(), tan(), tanh()
```

Example:

```
#include <math.include>
#define PI 3.141592654

main()
{

   double y, x=PI/2;

   y = cos(x);
   printf("The cosine of %f is %f.", x, y);
   getch();
}
```

Library Functions

cosh( )

Format:

```
#include <math.include>

double cosh(x)
double x;
```

Description:

Calculates the hyperbolic cosine of x.

Return Values:

Returns the hyperbolic cosine of x (a value between 1 and -1).

See Also:

```
acos(), asin(), atan(), atan2(), cos(), cotan(), sin(), sinh(), tan(), tanh()
```

Example:

```
#include <math.include>
#define PI 3.141592654

main()
{

    double y, x=PI/2;

    y = cosh(x);
    printf("The hyperbolic cosine of %f is %f.", x, y);
    getch();
}
```

cotan( )

Format:

```
#include <math.include>

double cotan(x)
double x;
```

Description:

Calculates the cotangent of x.

Return Values:

Returns the cotangent of x.

See Also:

```
acos(), asin(), atan(), atan2(), cos(), cosh(), sin(), sinh(), tan(), tanh()
```

cotan( )

Example:

```
#include <math.include>
#define PI 3.141592654

main()
{
   double radx, degx, x=0.5;

   radx = cotan(x);
   degx = radx * 180/PI;

   printf("The cotangent of %f is %f degrees or %f in radians.", x, degx,radx);
   getch();
}
```

cursor_off( )

Format:

```
void cursor_off()
```

Description:

Makes the cursor invisible.

Return Values:

None

See Also:

```
cursor_on()
```

Example:

```
main()
{
    cursor_on();
    printf("Press a key: ");
    getch();
    printf("\n");
    cursor_off();
    printf("Press a key: \n");
    getch();
}
```

cursor_on()

Format:

```
void cursor_on()
```

Description:

Makes the cursor visible.

Return Values:

None

See Also:

```
cursor_off()
```

Example:

```
main()
{
    cursor_off();
    printf("Press a key: \n");
    getch();
    cursor_on();
    printf("Press a key: ");
    getch();
}
```

Library Functions

display_keys_on()

Format:

```
int display_keys_on()
```

Description:

Sends a message to the display telling it to put itself in the keyboard-on state. The process which is sharing the keyboard with the display should have one softkey labeled `Display Control`, and if that softkey is pressed, the process should: 1) unlock the keyboard; 2) call `display_keys_on()`; and 3) refrain from painting any softkeys or getting keys until it receives a `KEYS_OFF` (`DISPLAY` type) message from the display (see `start_display()` for more information on `DISPLAY` messages).

Note This function is only needed when a display process has been activated (using `start_display()`) with the `share_keyboard` parameter equal to 1. In this case, the display and the process that called `start_display()` may take turns controlling the softkey labels and the `stdin` stream.

The display takes over keyboard control when the process calls `display_keys_on()`, and it gives up control by sending a message of type `DISPLAY` and subtype `STOPPED` to the parent process (the `STOPPED` message may be triggered by pressing the top-level `Stop Run` key, which the display process generates).

Return Values:

0	The message was sent.
-1	The queue has been deleted
-2	An invalid queue number was given.

Library Functions

-3	Out of memory.
-5	Out of memory.
-6	The queue was full.

See Also:

start_display(), stop_display()

Example:

```
#include <stdio.include>    /* NULL                        */
#include <message.include>  /* MESSAGE, WAIT, WAIT_FOREVER */
#include <video.include>    /* NORMAL, INVERSE             */
#include <conio.include>    /* SK1-8                       */

main()
{
   MESSAGE message;
   int result, chr, my_keys_on;

   set_rows(17,21);
   keyboard_lock();
   result = start_display(NULL, 15, 1);
   printf("start_display() returned: %d \n",result);
   put_all_sks("","","","","","Display'Control","","'Exit",INVERSE);
   while(1)
   {
      chr = getch();
      switch(chr)
      {
```

display_keys_on()

```
        case SK6:  /* Display Control Key*/
            keyboard_unlock();
            result = display_keys_on();
            printf("display_keys_on() returned %d\n",result);
            my_keys_on = 0;
            while (!my_keys_on)
            {
                read_message(&message, WAIT, WAIT_FOREVER);
                printf("message type/subtype: %d / %d", message.type, message.subtype);
                if((message.type == DISPLAY) && (message.subtype == KEYBOARD_OFF))
                {
                    my_keys_on = 1;
                    keyboard_lock();
                    set_rows(17,25);
                    wipe(22,25);
                    set_rows(17,21);
                    put_all_sks("","","","","","Display‘Control","","‘Exit",INVERSE);
                }
            }
            break;
        case SK8:  /* Exit Key*/
            stop_display();
            exit();
        default:
            break;
        }
    }
}
```

eq_file_time()

Format:

```
int eq_file_time(file_1, file_2)
char *file_1;
char *file_2;
```

Description:

This function compares two files to determine which was modified more recently.

Return Values:

-2	An error occurred during an attempt to open one of the files.
-1	The modify time of `file_1` < modify time of `file_2`
0	The modify time of `file_1` = modify time of `file_2`
1	The modify time of `file_1` > modify time of `file_2`

Library Functions

Example:

```
main()
{

    int result;

    result = eq_file_time("file1.text","file2.text");

    switch(result)
    {
        case -2:
            printf("all of the necessary files cannot be found");
            break;
        case -1:
            printf("file1.text is older than file2.text");
            break;
        case 0:
            printf("the files have the same time stamp!");
            break;
        case 1:
            printf("file2.text is older than file1.text");
            break;
    }
    getch();
}
```

error_notification( )

Format:

```
#include <message.include>

void error_notification(yelp_msg_ptr, error_subtype)
char *yelp_msg_ptr, error_subtype;
```

Description:

Sends an error message to the `error_QID`. There are two error subtypes: `FATAL_ERROR` and `NON_FATAL_ERROR`.

Return Values:

None

See Also:

```
set_error_handler()
```

Example:

```
#include <message.include>

main()
{

    error_notification("Out of Memory",NON_FATAL_ERROR);
}
```

examine_data()

Format:

```
#include <system.include>

int examine_data(path_name, priority)
char *path_name;
int priority;
```

Description:

Allows the DataCommC examine data process to be spawned programmatically. The process does not share the keyboard with other processes, and it uses the entire screen for its display. Once running, the examine data process can only be terminated when the top-level **Exit** softkey, which it generates, is pressed.

If the `path_name` parameter is `NULL`, the default examine data process is used (the default program is: `c:C/System/Bin/ExamEvents.program`). `NULL` is defined in the `stdio.include` file.

The examine data process should be given a priority number between 1 and 199. If the priority is not within this range, `priority` is set to `DEFAULT_PRIORITY`, which is defined (in `system.include`) to be 100.

Library Functions

Return Values:

0	The process was spawned.
-1	The program was not found.
-2	There was no memory for the process.
-3	Invalid program file format found.
-15 to -19	Can't communicate with ROOT process.
-21	No message queues were available.

examine_data()

-22	Can't notify process manager.
-41	Too many processes.
-42	No memory for user stack.
-43	User stack was too small.

See Also:

`start_display(), spawn()`

Example:

```
#include <system.include>
#include <stdio.include>

main()
{
    examine_data(NULL, DEFAULT_PRIORITY);
}
```

exit( )

Format:

```
void exit(exit_val)
int exit_val;
```

Description:

Closes files and exits a process. If the process was spawned with `spawnw()`, `exit_val` is returned to the calling process.

Return Values:

None

See Also:

```
spawn(), spawnw()
```

exit( )

Example:

```
main()
{

   int ch;

   printf("Press a key to be echoed to the screen");
   while(1)
   {
      ch = getch();
      if (ch > 31)
         putch(ch);
      else
         exit(1);
   }
}
```

exp( )

Format:

```
#include <math.include>

double exp(x)
double x;
```

Description:

Returns the exponential function of x.

Return Values:

Returns the result of the operation.

See Also:

```
log()
```

Example:

```
#include <math.include>

main()
{
double y, x = 10;

y = exp(x);

printf("The exponential of %f is %f.",x,y);
getch();
}
```

Library Functions

fabs( )

Format:

```
#include <math.include>

double fabs(x)
double x;
```

Description:

Calculates the absolute value of a number represented by a `double` (x).

Return Values:

Returns the absolute value of x.

See Also:

```
abs()
```

Example:

```
#include <math.include>

main()
{
   double i,j = -15.25;

   i = fabs(j);

   printf("The absolute value of %f is %f.",j,i);
   getch();
}
```

Library Functions

fclose( )

Format:

```
#include <stdio.include>

int fclose(file)
FILE *file;
```

Description:

Closes a file.

Return Values:

0	The file was closed successfully.
-1	An error occurred during the fclose operation.

See Also:

fopen()

Library Functions

fclose( )

Example:

```
#include <stdio.include>

main()
{
   FILE *fptr;

   printf("Press a key to close testfile.csource: ");
   getch();
   if((fptr = fopen("testfile.csource","w")) != NULL)
   {
      fputs("hello world",fptr);
      fclose(fptr);
      printf("\nThe file was closed.");
   }
   else
      printf("Could not open file.");
   getch();
}
```

fflush( )

Format:

```
#include <stdio.include>

int fflush(file)
FILE *file;
```

Description:

Flushes the buffer associated with a file. The `fflush()` macro is defined in the `stdio.include` file.

Return Values:

0	The `fflush` operation was successful.
-1	An error occurred during the `fflush` operation.

Library Functions

fflush( )

Example:

```
#include <stdio.include>

main()
{
   FILE *fptr;

   printf("Press a key to flush the contents of testfile.csource:");
   if((fptr = fopen("testfile.csource","w")) != NULL)
   {
      fputs("hello world",fptr);
      fflush(fptr);
      fclose(fptr);
      printf("The file contents were flushed.");

   }
   else
      printf("Could not open file.");
   getch();
}
```

fgetc( )

Format:

```
#include <stdio.include>

int fgetc(file)
FILE *file;
```

Description:

Gets the next character from a file. This macro is defined in the `stdio.include` file.

Return Values:

Returns the character.

See Also:

```
ungetc(), fgets()
```

Example:

```
#include <stdio.include>

main()
{
    int inchar;

    inchar = fgetc(stdin);
    printf("The character read from the input is %c.", inchar);
    getch();
}
```

Library Functions

fgets( )

Format:

```
#include <stdio.include>

char *fgets(str, n, file)
char *str;
int n;
FILE *file;
```

Description:

Reads up to `n-1` characters from a file or up to the first newline character ('\n'), or until end-of-file, whichever comes first. The string `str` is terminated with a `NULL` character ('\0').

Return Values:

Returns a pointer to the string.

See Also:

```
fputs(), fgetc(), ungetc()
```

Library Functions

Example:

```
#include <stdio.include>

main()
{
   char instr[70];

   fgets(instr,70,stdin);
   printf("The string read from the input is %s.", instr);
   getch();
}
```

file_time( )

Format:

```
int file_time(name, year, month, day, hour, min, sec)
char *name;
char year[3];
char month[3];
char day[3];
char hour[3];
char min[3];
char sec[3];
```

Description:

Returns the time when the specified file was last modified. The file is specified in the `name` parameter, which must contain the device, path and file name. The `file_time` function returns each of the `year`, `month`, `day`, `hour`, `min` and `sec` parameters as ASCII, null-terminated string.

Return Values:

0	The function was successful.
-1	The file name could not be found.

See Also:

`eq_file_time()`

Library Functions

Example:

```
main()
{
   char year[3], month[3], day[3], hour[3], min[3], sec[3];

   if(file_time("file1.text", year, month, day, hour, min, sec) == 0)
      printf("file1.text was last modified on %s/%s/%s at %s:%s:%s.",
         month, day, year, hour, min, sec);
   else
      printf("Error returned from file time.");
   getch();
}
```

Library Functions

filln( )

Format:

```
void filln(n,ptr,fill)
int n;
char *ptr;
char fill;
```

Description:

Fills n bytes with a fill character, beginning at ptr.

Return Values:

None

Example:

```
main()
{
    char buff[81];

    printf("Enter a string of characters and press RETURN\n");
    gets(buff);
    printf("The buffer contains: %s\n",buff);
    filln(strlen(buff),buff,'/000');    /* initialize the buffer to 0's */
    printf("After filln(), the buffer contains: %s",buff);
    getch();
}
```

floor( )

Format:

```
#include <math.include>

double floor(x)
double x;
```

Description:

Returns the largest integer not greater than x.

Return Values:

Returns the value of the next smaller integer.

See Also:

```
ceil()
```

Example:

```
#include <math.include>

main()
{
double x = 1.25;
double x1;

x1 = floor(x);
printf("floor(%f) is %f.",x,x1);
getch();
}
```

Library Functions

fopen( )

Format:

```
#include <stdio.include>

FILE *fopen(name, access_mode)
char *name;
char *access_mode;
```

Description:

Opens the file specified by the name parameter. The access_mode parameter gives the type of access requested for the file, as shown below:

access_mode	Description
"r"	Opens the file for reading only. If the file does not exist or cannot be found, an error is returned.
"w"	Opens an empty file for writing. If the given file already exists, its contents are destroyed.
"a"	Opens a file for appending. The calling program is granted write-only access. The current file position is the character after the last character in the file. If the file does not exist, it is created.
"r+"	Opens the file for both reading and writing. If the file does not exist or cannot be found an error is returned.
"w+"	Opens the file for both reading and writing. If the file already exists, its contents are destroyed.
"a+"	Opens a file for both reading and appending. If the file does not exist, it is created.

Note The "w" and "w+" access modes destroy existing files; they should be used only with extreme caution.

Only new files opened using the "w" or "w+" modes are allowed to grow without limit (if disc space allows). All other existing files can only be read or written to the end of the physical file size. Additionally, only one new file may be opened in "w" or "w+" mode at one time on each disc unit. If more than one file must be written to at the same time, all of them, or all but one must have been previously created and must exist prior to calling `fopen()`. Files may be created in this way with `make_file()`.

Return Values:

Returns a pointer to the opened file, or `NULL` if an error occurred.

See Also:

`fclose(), fread(), fseek(), fwrite(), open()`

fopen( )

Example:

```
#include <stdio.include>

main()
{
   FILE *fptr;

   if((fptr = fopen("testfile.csource","w")) != NULL)
   {
      printf("testfile.csource was opened.");
      fclose(fptr);
   }
   else
      printf("Could not open file.");
   getch();
}
```

fprintf( )

Format:

```
int fprintf(file, format, args)
FILE *file;
char *format;
char *args;
```

Description:

Outputs arguments in `args` to an output stream or file (`file`) according to `format`.

The character string pointed at by `format` directs the output operation, and contains two types of information: ordinary alphanumeric characters, which are output unchanged; and conversion specifications, each of which causes the conversion and output of the next argument in the `args` list.

The formatted string is output from left to right. When a conversion specification is encountered, the next (initially first) argument is output according to the conversion specification.

A conversion specification has the form:

```
%[flag] [width] [.precision] [l] type
```

Each field enclosed in braces "`[ ]`" is optional and consists of a single character or number signifying a particular format option. The simplest possible conversion specification contains a percent sign (`%`) and a conversion character (ex: `%f`).

`flag`

- The converted argument is left-justified when printed (the default is right-justification).

Library Functions

`width`

digit string The numeric digit string specifies the field width for the conversion. If the converted value has fewer characters than `width`, enough blank (space) characters are output to make the total number of characters output equal the field width. The spaces are output before or after the value, depending on the presence or absence of the left-justification flag. If the field width digits have a leading zero, zeros are used as pad characters instead of spaces.

* The `width` parameter is supplied by the corresponding argument in the argument list (`args`). The argument must be of type `int`.

`.precision`

digit string For floating point conversions, `precision` specifies the number of digits to appear after the decimal point; for character string conversions, it specifies the maximum number of characters to be printed from a string.

* The `precision` parameter is supplied by the corresponding argument in the argument list (`args`). The argument must be of type `int`.

`l`

A conversion normally performed on an `int` is performed on a `long` (may be used with the `d`, `o` and `x` conversion characters).

The type character format is as follows:

character	type of argument	output format
d	int	signed decimal
u	int	unsigned decimal
x	int	unsigned hexadecimal
o	int	unsigned octal
f	float or double	floating point
c	char	single character
s	string	character string
e	float or double	scientific nototation
g	uses d, f or e - whichever gives	full precision in minimum space

fprintf( )

Return Values:

Returns the number of characters printed.

See Also:

```
printf(), sprintf()
```

Example:

```
#include <stdio.include>

main()
{
   FILE *fptr;

   if((fptr = fopen("testfile.csource","w")) != NULL)
   {
      fprintf(fptr,"%s","hello world");
      printf("The string \"hello world\" was placed in testfile.csource.");
      fclose(fptr);
   }
   else
      printf("Could not open file.");
   getch();
}
```

fputc( )

Format:

```
#include <stdio.include>

int fputc(ch, file)
int ch;
FILE *file;
```

Description:

Writes a single character to an output stream or file (`file`). This macro is defined in the `stdio.include` file.

Return Values:

Returns the character written.

See Also:

`fputs(), putc()`

Library Functions

fputc( )

Example:

```
#include <stdio.include>

main()
{
   FILE *fptr;
   char *outstr;

   outstr = "hello world";

   while(*outstr)
      fputc(*outstr++,stdout);
   fputc('\n',stdout);
   getch();
}
```

Library Functions

fputs( )

Format:

```
#include <stdio.include>

int fputs(str, file)
char *str;
FILE *file;
```

Description:

Takes the string indicated by the `str` parameter and places all the characters, up to but not including the end `NULL`, on an output stream or in the file described by `file`. If `file` is used to define the output stream as `stdout`, the string is sent to the standard output device (the protocol analyzer's display).

Return Values:

Zero if successful, nonzero if an error has occurred.

See Also:

`fgets(), puts()`

Example:

```
#include <stdio.include>

main()
{
    char *outstr;

    outstr = "hello world";
    fputs(outstr,stdout);
    getch();
}
```

fread( )

Format:

```
#include <stdio.include>

int fread(ptr, size, n, file)
char *ptr;
int size;
int n;
FILE *file;
```

Description:

Reads an array from a file or input stream and places the information in a storage area pointed to by the `ptr` parameter. The `size` and `n` parameters define the size (in bytes) of each array element and the number of elements in the array, respectively. If the `file` parameter indicates a file, and not an input stream, the associated file pointer is incremented.

Return Values:

Returns the number of elements actually read; this number may be smaller than `n` if an error occurred during the transfer or the end-of-file was found before all the elements were read.

See Also:

```
fwrite(), gets(), fputs()
```

fread()

Example:

```
#include <stdio.include>

main()
{
    char instr[70];
    int result;

    result = fread(instr, 1, 10, stdin);
    instr[result] = 0;
    printf("The string read from the input is %s.", instr);
    getch();
}
```

Library Functions

free( )

Format:

```
#include <stdlib.include>          /* for function declarations */

void free(ptr)
char *ptr;
```

Description:

This function deallocates a block of memory previously allocated by `malloc()` or `calloc()`. The size of the freed block is exactly the number of bytes requested in the `malloc/calloc` function call. Similarly, the pointer (`ptr`) passed to `free()` must be identical to the one returned by `malloc()` or `calloc()`.

Return Values:

None

See Also:

`calloc(), malloc()`

Library Functions

Example:

```
#include <stdlib.include>

main()
{
   char *str, *allocated_str;

   str="hello world";
   allocated_str=calloc(1,strlen(str) + 1); /* add 1 to the length for the NULL char. */
   strcpy(allocated_str,str);
   printf("The allocated_str is %s.",allocated_str);
   free(allocated_str);                     /* free the memory to the system */
   getch();
}
```

fscanf( )

Format:

```
int fscanf(file, format, args)
FILE *file;
char *format;
char *args;
```

Description:

Takes text characters from the specified stream (file), checks the character types against conversion characters imbedded in a control string pointed to by the format parameter, and places matching text in the fields pointed to by the args list.

The following fscanf() example shows the main components of the function:

```
fscanf("file1.text", "%f%s", &fltptr, &strptr);
```

The string "%f%s" is a control string (format) with two control items (both conversion characters), one indicating a floating point value (%f), and the other (%s) indicating a string. The other arguments, &fltptr and &strptr, define the argument list (args). If fscanf() finds floating point characters, it places them in the memory location pointed to by fltptr; if a character string is found next, it is placed in the memory location pointed to by strptr.

A control string contains these control items:

- Conversion specifications
- Optional white space characters (tab, space, newline)
- Optional alphanumeric characters (not white space, and not part of a conversion specification).

The fscanf function works its way through a control string from left to right, trying to match each control item to a portion of the input stream. During the matching process, fscanf() fetches characters one at a time from the input stream. If a character is found which doesn't match the type specifier for the corresponding conversion specificiation, fscanf() pushes the character back onto the input stream and finishes processing the current control item. This

"pushing back" frequently gives unexpected results when a stream is used later by other I/O functions, such as `getc()` or `scanf()`, as well as by `fscanf()` itself, if it is used again.

A conversion specification has the form:

```
%[*] [width] [l] type
```

Each field enclosed in braces "[ ]" is optional and consists of a single character or number signifying a particular format option. The simplest possible conversion specification contains a percent sign (%) and a conversion character (ex: %f)

The optional fields are defined below, and conversion characters are discussed later in this segment.

`*`

Assignment suppression character. The current stream is scanned, but not saved. The function goes on to the next control string item.

`width`

This field specifies the maximum number of characters to be fetched for the conversion.

`l`

This field indicates that the argument is a pointer to a long data type - the exact type (for example, long decimal, long hex, long unsigned) is determined by the conversion character.

fscanf( )

The conversion character format is as follows:

character	type of argument	expected input format
d	pointer to int	signed decimal
u	pointer to int	unsigned decimal
x	pointer to int	unsigned hexadecimal
o	pointer to int	unsigned octal
e,f	pointer to float	floating point
c	pointer to char	single character
s	pointer to char array	character string

When a conversion specification is encountered in the control string, the `fscanf` function skips leading white space on the input stream, then collects characters from the stream until it encounters one that is not appropriate for the corresponding conversion character. That character is pushed back onto the input string.

As long as the conversion specification didn't request assignment suppression (see '*', above), the text string that was read from the keyboard is converted to the format specified by the conversion specification, the result is placed in the location pointed to by the corresponding args argument, the next argument becomes current, and the function proceeds to the next control string item.

If assignment suppression was requested, the `fscanf` function ignores the input characters and goes on the the next control item.

If an ordinary character is found in the control string, outside any conversion specfication, `fscanf()` fetches the next character. If that character matches the character in the control string, the function goes on to the next control string item, ignoring the input character. If there is no match, `fscanf()` terminates.

If a white space character is found in the control string, the `fscanf` function fetches input characters until the first non-white space character is read. The non-white space character is pushed back onto the input stream and `fscanf()` proceeds to the next item in the control string.

Return Values:

Returns the number of items converted and assigned to memory locations in `args`. Unmatched items, since they are not assigned to `args`, are not included in the count. `fscanf()` returns `EOF` if an attempt is made to read past the end of the file.

See Also:

`scanf(), sscanf()`

Example:

```
#include <stdio.include>

main()
{
    char instr[70];

    fscanf(stdin,"%s",instr);
    printf("The string read from the input is %s.", instr);
    getch();
}
```

Library Functions

fseek( )

Format:

```
#include <stdio.include>

int fseek(fptr, offset, origin)
FILE *fptr;
long offset;
int origin;
```

Description:

Moves the file pointer `fptr` to a location in the file `offset` bytes from the `origin`. The `fptr` parameter must be the file pointer returned by `fopen()`. Constant values for `origin` are defined in the `stdio.include` file, and are described below:

origin	Description
SEEK_SET	The file pointer indicates the beginning of the file.
SEEK_CUR	The file pointer indicates the current position in the file.
SEEK_END	The file pointer indicates the end of the file.

Library Functions

Return Values:

Returns zero if the function was successful, or -1 if an error occurred during the operation.

See Also:

`lseek()`

Example:

```
#include <stdio.include>

main()
{
   FILE *fptr;
   int open_result, seek_result, write_result;
   char instr[20];

   if((fptr = fopen("file1.text","w")) == NULL)
      printf("Can't open file1.text.");

   else
   {
      write_result = fwrite("hello world\n",1,10,fptr);
      if((seek_result = fseek(fptr,7L,SEEK_SET)) != 0)
         printf("Seek error detected.");
      else
      {
         fclose(fptr);
         if((fptr = fopen("file1.text","r")) == NULL)
            printf("Can't open file1.text.");
         else if ((seek_result = fseek(fptr,7L,SEEK_SET)) != 0)
            printf("Seek error detected.");
         else
         {
            fgets(instr,3,fptr);
            printf("the string read after fseek is %s.",instr);
         }
      }
   }
   getch();
}
```

ftoa( )

Format:

```
#include <stdlib.include>

void ftoa(val,buf,precision,type)
double val;
char *buf;
int precision,type;
```

Description:

Converts a floating-point or double precision number to an ASCII character string.

The `val` parameter is the number to be converted and `buf` points to the buffer where the ASCII string will be placed. The `precision` parameter specifies the number of digits to the right of the decimal point, and `type` specifies the format: 0 for "`E`" format, 1 for "`F`" format, and 2 for "`G`" format.

Return Values:

None

See Also

`atof()`

Example:

```
#include <stdlib.include>

main()
{
    char str[25];
    double dvar;

    dvar = 3.456;
    ftoa(dvar,str,3,2);
    printf("%s ascii was converted from %f.",str,dvar);
    getch();
}
```

fwrite( )

Format:

```
#include <stdio.include>

int fwrite(ptr, size, n, file)
char *ptr;
int size;
int n;
FILE *file;
```

Description:

Writes an array to a file or output stream. The `fwrite` function reads an array from a buffer pointed to by the `ptr` parameter, and places the information in a file or output stream. The `size` and `n` parameters define the size (in bytes) of each array element and the number of elements in the array, respectively. If the `file` parameter indicates a file, and not an output stream, the associated file pointer is incremented.

Return Values:

Returns the number of elements actually written; this number may be smaller than `n` if an error occurred during the transfer.

See Also:

```
fread()
```

Example:

```
#include <stdio.include>

main()
{
   FILE *fptr;
   char *outstr;

   outstr = "hello world";
   if((fptr = fopen("testfile.csource","w")) != NULL)
   {
      fwrite(outstr,1,strlen(outstr),fptr);
      printf("The string \"hello world\" was written to testfile.csource.");
      fclose(fptr);
   }
   else
      printf("Could not open file.");
   getch();
}
```

get_attribute( )

Format:

```
#include <video.include>

int get_attribute()
```

Description:

Returns the value of the current display attribute. The attribute determines the form of any text printed to the screen, and generates ASCII, hex or EBCDIC character sets in normal, inverse-video, low-intensity or blinking modes. Any of the attributes for a given character set may be arithmetically OR'd together to form a combination of effects.

The `UNDERLINE` attribute allows any of the characters in the ASCII, hex or EBCDIC character sets to be underlined when they appear on the screen.

Additionally, the `SPECIAL` attribute allows access to four sets or banks of graphics characters. These individual banks may be selected with the `set_disp_bank` function after the `SPECIAL` attribute is active. See `set_disp_bank()` in this chapter.

The constant values available for the `attribute` parameter are located in the `video.include` file and are also shown in this segment.

Return Values:

The `get_attribute` function may return almost any combination of these constant values, since `set_attribute()` may arithmetically OR the attributes together. For this reason, it is a good idea to take the return value and arithmetically AND it with the constant value of the attribute you are testing.

ASCII attribute	value
NORMAL	0x0200
INVERSE	0x0600
BLINK	0x0A00
HALF_BRIGHT	0x1200

Hex attribute	value
HEX_NORMAL	0x0000
HEX_INVERSE	0x0400
HEX_BLINK	0x0800
HEX_HALF_BRIGHT	0x1000

EBCDIC attribute	value
EBCDIC_NORMAL	0x0100
EBCDIC_INVERSE	0x0500
EBCDIC_BLINK	0x0900
EBCDIC_HALF_BRIGHT	0x1100

Underline attribute	value
UNDERLINE	0x2000

Graphics attribute	value
SPECIAL	0x0300

See Also:

set_attribute(), set_disp_bank(), set_screen_mode()

get_attribute( )

Example:

```
#include <video.include>

main()
{
    int attribute;
    attribute = get_attribute();
    printf("The following screen attributes are set:\n\n");

    if( (attribute &  NORMAL) == NORMAL)
        printf("        NORMAL\n");
    if( (attribute &  SPECIAL) == SPECIAL)
        printf("        SPECIAL\n");
    if( (attribute &  INVERSE) == INVERSE)
        printf("        INVERSE\n");
    if( (attribute &  HALF_BRIGHT) == HALF_BRIGHT)
        printf("        HALF_BRIGHT\n");
    if( (attribute &  BLINK) == BLINK)
        printf("        BLINK\n");
    if ( (attribute & NORMAL) == 0)
    {
        if( attribute &  HEX_NORMAL)
            printf("        HEX_NORMAL\n");
        if( attribute &  HEX_INVERSE )
            printf("        HEX_INVERSE\n");
        if( attribute & HEX_BLINK )
            printf("        HEX_BLINK\n");
    }
    getch();
}
```

Library Functions

get_bitrate( )

Format:

```
#include <retval.include>

int get_bitrate(bitrate)
long *bitrate;
```

Description:

Puts the value of the currently selected bitrate into the memory location pointed to by the `bitrate` parameter.

Return Values:

`SUCCESSFUL (0)` There is no error return code.

See Also:

```
set_bitrate()
```

Example:

```
main()
{
    long bitrate;

    get_bitrate(&bitrate);
    printf("The bitrate is %ld.",bitrate);
    getch();
}
```

Library Functions

get_channelconfig( )

Format:

```
#include <dlib.include>
#include <retval.include>

int channelconfig(channel, config)
char channel;
char *config;
```

Description:

Checks the configuration for the channel specified by the `channel` parameter, then puts the information into the memory location pointed to by the `config` parameter. Constant values for both parameters are in the `dlib.include` file; valid values are also shown below:

channel	value
DTE	0x1
DCE	0x2
SDTE	0x4
SDCE	0x5

config	value
NONE	0x0
RX	0x1
TX	0x2

Library Functions

Return Values:

SUCCESSFUL (0)

WARNING_1 (1) The value specified for `channel` is unknown. It is assumed to be the default, `DCE`, and the `DCE` configuration is passed back to `config`.

See Also:

set_channelconfig()

Example:

```
#include <dlib.include>
#include <retval.include>

main()
{
   char config;
   int result;

   printf("\n");

   if( (result = get_channelconfig(DTE,&config)) == SUCCESSFUL )
      printf("The DTE channel configuration is %d.",config);
   else
      printf("get_channelconfig() error #%d.",result);
   getch();
}
```

get_cursor()

Format:

```
void get_cursor(row, column)
int *row, *column;
```

Description:

Puts the current row and column position of the cursor into the memory locations pointed to by the `row` and `column` parameters, respectively.

Return Values:

None

See Also:

```
set_cursor()
```

Example:

```
main()
{
    int row, col;

    get_cursor(&row, &col);
    printf("Prior to this printf(), the cursor was at row %d, column %d.",row, col);
    getch();
}
```

get_data_source()

Format:

```
#include <dlib.include>
#include <retval.include>

int get_data_source(data_source, data_file)
char *data_source;
char *data_file;
```

Description:

Puts the constant value of the currently selected data source device into the memory location pointed to by the data_source parameter. The data source device, which may be defined as either the line or one of the protocol analyzer's discs, indicates from where the event message information for the read_message function should be read. The valid constant values are:

data source	value
LINE_RUN	0x2
DISC_RUN	0x3

If data_source contains the DISC_RUN value, the data_file parameter points to a character string representing the path name and file name of the data source. The path name determines which disc has been selected. The protocol analyzers' internal drives are identified by a: (the flexible disc drive) and c: (the hard disc drive), but any external drives may be used as well. See the *DataCommC User's Guide* for a list of possible disc drive path names.

Return Values:

SUCCESSFUL (0) There is no error return code.

Library Functions

get_data_source()

See Also:

set_data_source()

Example:

```
#include <dlib.include>

main()
{
   char source;
   char filename[81];
   char *source_str[2];

   source_str[0] = "Line";
   source_str[1] = "Disc";

   get_data_source(&source,filename);
   printf("The system processes data from the %s.\n",source_str[source-2]);

   if(source == DISC_RUN)
      printf("The file name is %s.",filename);
   getch();
}
```

get_datacode( )

Format:

```
#include <dlib.include>
#include <retval.include>

int get_datacode(datacode)
int *datacode;
```

Description:

Puts a constant value representing the currently selected datacode into the memory location pointed to by the datacode parameter. The following datacode values are located in the dlib.include file.

datacode	value
ASCII8	0x0001
ASCII7	0x0002
EBCDIC	0x0003
HEX8	0x0004
HEX7	0x0005
HEX6	0x0006
HEX5	0x0007
USER_DEF	0x0008

These datacode values can be modified using the set_protocol function. The get_datacode function may be called while the data link control hardware is running.

Return Values:

SUCCESSFUL (0) There is no error return code.

get_datacode()

See Also:

set_protocol()

Example:

```
#include <dlib.include>

main()
{
    int datacode;

    get_datacode(&datacode);
    printf("The datacode is %d.",datacode);
    getch();
}
```

Library Functions

get_dir()

Format:

```
char *get_dir(pathname)
char pathname[82];
```

Description:

Puts a character string representing the path name of the current drive/directory/subdirectory path into the memory location pointed to by the `pathname` parameter.

Return Values:

Returns a pointer to the path name.

See Also:

`ch_dir(), makedir(), parsedir()`

Example:

```
main()
{
   char dir[82];

   get_dir(dir);
   printf("The current directory is %s.\n", dir);
   getch();
}
```

get_duplex( )

Format:

```
#include <dlib.include>
#include <retval.include>

int get_duplex(duplex)
int *duplex;
```

Description:

Puts the duplex value for the conversation between DTE and DCE devices into the memory location pointed to by the `duplex` parameter. The constant value may be either:

duplex	value
HDX	1
FDX	2

These values are located in the `dlib.include` file.

The duplex values may be modified using the `set_duplex` function. The `get_duplex` function may be called while the data link control hardware is running.

Return Values:

`SUCCESSFUL (0)` There is no error return code.

See Also:

`set_duplex()`

Library Functions

Example:

```
#include <dlib.include>
#include <retval.include>

main()
{
    int duplex;

    set_duplex(FDX);
    get_duplex(&duplex);

    if(duplex != FDX)
    {
        printf("get_duplex() doesn't match the set\n");
    }
    else
            printf("The set_duplex() worked\n");
        getch();
}
```

get_errorcheck( )

Format:

```
#include <dlib.include>
#include <retval.include>

int get_errorcheck(errorcheck)
int *errorcheck;
```

Description:

Puts a constant value representing the currently selected errorcheck type into the memory location pointed to by the errorcheck parameter. The following errorcheck values are located in the dlib.include file.

errorcheck	value
CRC_16	0x1
CRC_CCITT	0x2
NO_ERROR_CHECK	0x3
CRC_12	0x4
LRC	0x5
CRC_6	0x6

These errorcheck values can be modified using set_protocol() or the protocol analyzer's Setup Menu. The get_errorcheck function may be called while the data link control hardware is running.

Return Values:

SUCCESSFUL (0) There is no error return code.

See Also:

```
set_protocol()
```

Example:

```
#include <dlib.include>

main()
{
    int errorcheck;

    get_errorcheck(&errorcheck);
    printf("The errorcheck type is %d.",errorcheck);
    getch();
}
```

get_event_bounds( )

Format:

```
#include <retval.include>
#include <message.include>

int get_event_bounds(num_events, first_event, last_event)

int *num_events;
void **first_event, **last_event;
```

Description:

Puts pointers to the event buffer's first and last events into the memory locations pointed to by the `first_event` and `last_event` parameters, respectively. This function can only be called at the conclusion of a run, that is, after starting and stopping the data link control hardware with the `start_data()` and `stop_data()` functions. The number of complete events is placed in the memory location pointed to by `num_events`. If the buffer is empty, `*num_events` contains zero and the pointers are set to `NULL`.

Return Values:

SUCCESSFUL (0)

ERROR_10 (-10)   The dlc hardware was running.

See Also:

`hold_event(), release_event()`

Example:

```
#include <retval.include>
#include <message.include>
#include <dlib.include>

main()
{
   void *first_event, *last_event;
   MESSAGE *msg;
   int num_events, event_counter = 0;
   int result;

   if( (result = start_data()) != SUCCESSFUL )
   {
      printf("Error starting DLC hardware.\n");
      exit();
   }
   printf("Press a key to stop event collection: ");
   putc('\n');
   sendf("Hello world");    /* make sure the 4954 is configured to transmit */
   getch();
   stop_data();

   get_event_bounds(&num_events, &first_event, &last_event);
   printf("The first event is stored at address %lx hex.\n",first_event);
   printf("The last event is stored at address %lx hex.\n",last_event);
   msg = first_event;
   while (event_counter++ < num_events)
   {
      print_event(msg);     /* call user routine to print the message */
      if(msg++ == BOTTOM_EVENT)
         msg = TOP_EVENT;
   }
   getch();
}
```

Library Functions

get_event_bounds()

```
print_event(msg) /* user routine to display the event */
MESSAGE *msg;
{
   printf("The message type is %d the subtype is %d.\n",msg->type, msg->subtype);
}
```

Library Functions

get_ignored_leads( )

Format:

```
#include <leads.include>
#include <retval.include>

int get_ignored_leads(lead_id_map)
long *lead_id_map;
```

Description:

Puts the currently selected set of ignored leads for the data link control hardware into the memory location pointed to by the `lead_id_map` parameter. The constants used in `lead_id_map` are defined in the `leads.include` file (see chapter 4 for listings of the include files).

get_ignored_leads()

Return Values:

SUCCESSFUL (0) There is no error return code.

See Also:

set_ignored_leads

Example:

```
#include <leads.include>

main()
{
    long lead_id_map;

    get_ignored_leads(&lead_id_map);

    if(lead_id_map & RTS)
        printf("RTS state changes ignored.\n");
    if(lead_id_map & CTS)
        printf("CTS state changes ignored.\n");
    if(lead_id_map & DSR)
        printf("DSR state changes ignored.\n");
    if(lead_id_map & DTR)
        printf("DTR state changes ignored.\n");
    printf("The lead_id_map is %lx.\n",lead_id_map);
    getch();
}
```

get_lead( )

Format:

```
#include <leads.include>
#include <retval.include>

int get_lead(lead_id, lead_state, message_ptr)
char lead_id, lead_state;
MESSAGE *message_ptr;
```

Description:

Checks to see if the state of the the lead associated with the DATACOMM message at the top of the incoming message queue matches the specified `lead_state`. The lead can be either ON, OFF, or DONT_CARE. If there is no DATACOMM message in the queue, an error is returned. The constant values available for the `lead_id` parameter are defined in the `leads.include` file (see chapter 4 for a complete listing); the names of the constants are shown below:

get_lead( )

Return Values:

SUCCESSFUL (0) The top message (pointed to by message_ptr) is a DATACOMM message with the lead specified by lead_id in the state specified by lead_state.

WARNING_1 (1) The message at the top of the queue is not a DATACOMM message. The message_ptr parameter is set to point to that message.

WARNING_2 (2) The lead is not in the specified state. The message_ptr parameter is set to point to the message at the top of the queue.

ERROR_1 (-1) There wasn't any message in the queue when it was polled. The message_ptr parameter is set to NULL.

See also:

set_lead()

Example:

```
#include <message.include>
#include <leads.include>
#include <dlib.include>
#include <retval.include>

main()
{
   MESSAGE datacomm_message;

   start_data();
   while(1)
   {
      if(is_msg_avail())
      {
         switch(get_lead(RTS,ON,&datacomm_message))
         {
            case SUCCESSFUL:
               printf("RTS has been set ON.\n");
               release_event(datacomm_message.body.event.event_ptr);
               break;
            case WARNING_1:
               printf("The message was not a Datacomm message.\n");
               release_event(datacomm_message.body.event.event_ptr);
               break;
            case WARNING_2:
               release_event(datacomm_message.body.event.event_ptr);
               break;
            case ERROR_1:
               printf("There is no message in the datacomm queue.\n");
               break;
         }
      }
   }
}
```

get_lead_control( )

Format:

```
#include <dlib.include>

int get_lead_control(lead_control)
int *lead_control;
```

Description:

Puts the lead_control value for the conversation between the DTE and DCE devices into the memory location pointed to by the lead_control parameter. The constant value is either:

lead_control	value
LEAD_CONTROL_DEFAULT	2
LEAD_CONTROL_USER_DEF	1

These lead_control values are located in the dlib.include file.

Return Values:

SUCCESSFUL (0) There is no error return code.

See also:

set_lead_control()

Example:

```
#include <dlib.include>
#include <retval.include>

main()
{
   int lead_control;

   set_lead_control(LEAD_CONTROL_USER_DEF);
   get_lead_control(&lead_control);

   if(lead_control != LEAD_CONTROL_USER_DEF)
      printf("get_lead_control() doesn't match the set\n");
   else
      printf("set_lead_control() worked\n");
   getch();
}
```

get_mode()

Format:

```
#include <dlib.include>
#include <retval.include>

int get_mode(mode)
int *mode;
```

Description:

Puts a constant value representing the the currently selected synchronization mode into the memory location pointed to by the mode parameter. The following mode values are located in the dlib.include file.

mode	value
ASYNC_1	0x1
ASYNC_1_5	0x2
ASYNC_2	0x3
SYNC_DCE	0x4
SYNC_NRZI	0x5
SYNC_DTE	0x6

These mode values can be modified using set_protocol() or the protocol analyzer's Setup Menu. The get_mode function may be called while the data link control hardware is running.

Return Values:

SUCCESSFUL (0) There is no error return code.

See Also:

set_protocol()

Example:

```
#include <dlib.include>
#include <retval.include>

main()
{
    int mode;
    int result;

    if( (result = get_mode(&mode)) != SUCCESSFUL)
    {
        printf("Error #%d returned from get_mode().\n",result);
        getch();
        exit();
    }
    switch (mode)
    {
        case SYNC_DTE:
            printf("The 4954 clock source is the DTE clock.");
            break;
        case SYNC_DCE:
            printf("The 4954 clock source is the DCE clock.");
            break;
        default:
            printf("The value of the synchronization mode is %d.",mode);
    }
    getch();
}
```

get_parity()

Format:

```
#include <dlib.include>
#include <retval.include>

int get_parity(parity)
int *parity;
```

Description:

Puts a constant value representing the the currently selected parity into the memory location pointed to by the parity parameter. The following constant values are located in the dlib.include file:

parity	value
ODD_PARITY	0x1
EVEN_PARITY	0x2
NO_PARITY	0x3
IGNORE	0x4

These parity values can be modified using set_protocol() or the protocol analyzer's Setup Menu. The get_parity function may be called while the data link control hardware is running.

Return Values:

SUCCESSFUL (0) There is no error return code.

See Also:

set_protocol()

Example:

```
#include <dlib.include>

main()
{
    int parity;

    get_parity(&parity);
    switch(parity)
    {
        case ODD_PARITY:
            printf("The 4954's parity is odd.");
            break;
        case EVEN_PARITY:
            printf("The 4954's parity is even.");
            break;
        case NO_PARITY:
            printf("The 4954 is not interpreting the parity bit.");
            break;
        case IGNORE:
            printf("The 4954 is ignoring parity.");
            break;
        default:
            printf("The parity type is %d.",parity);
    }
    getch();
}
```

get_protocol()

Format:

```
#include <dlib.include>
#include <retval.include>

int get_protocol(protocol)
int *protocol;
```

Description:

Puts the the value of the currently selected protocol into the memory location pointed to by the `protocol` parameter. The following protocol values are located in the `dlib.include` file.

protocol	value
BSC	0x1
SDLC	0x2
HDLC	0x3
X25	0x4
COPS	0x5
X75	0x7

These protocol values can be modified using the `set_protocol` function or the protocol analyzer's Setup Menu. The `get_protocol` function may be called while the data link control hardware is running.

Return Values:

`SUCCESSFUL (0)` There is no error return code.

See Also:

`set_protocol()`

Example:

```
#include <dlib.include>

main()
{
    int protocol;

    get_protocol(&protocol);
    switch(protocol)
    {
        case BSC:
            printf("The 4954's protocol is BSC.");
            break;
        case SDLC:
            printf("The 4954's protocol is SDLC.");
            break;
        case HDLC:
            printf("The 4954's protocol is HDLC.");
            break;
        case X25:
            printf("The 4954's protocol is X.25.");
            break;
        case COPS:
            printf("The 4954's protocol is COPS.");
            break;
        case X75:
            printf("The 4954's protocol is X.75.");
            break;
        default:
            printf("The protocol type is %d.",protocol);
    }
    getch();
}
```

get_resyncafter( )

Format:

```
#include <dlib.include>
#include <retval.include>

int get_resyncafter(numafter)
int *numafter;
```

Description:

Puts the currently selected resyncafter value into the memory location pointed to by the `numafter` parameter. When the protocol is COPS and the resync mode is AUTO, the resyncafter value represents the amount of time (in number of characters received) that the protocol analyzer waits after it has received a block check character (bcc) before it drops sync.

Return Values:

SUCCESSFUL (0)

ERROR_1 (-1) The protocol is not COPS.

ERROR_2 (-2) The mode is not AUTO.

See Also:

get_resynchars(), get_resyncmode(), resync(), set_resync(), set_protocol()

get_resyncafter( )

Example:

```
#include <dlib.include>

main()
{
    int resync_bytes;

    get_resyncafter(&resync_bytes);
    printf("The 4954 is configured to resync %d bytes after the sync is dropped."
                                                        ,resync_bytes);
    getch();
}
```

get_resynchars( )

Format:

```
#include <dlib.include>
#include <retval.include>

int get_resynchars(itext,otext1,otext2,otext3,otext4,otext5,otext6);
char *itext, *otext1, *otext2, *otext3, *otext4, *otext5, *otext6;
```

Description:

Puts the values of the currently selected resynchars (intext and outoftext) into the memory locations pointed to by the `itext` and `otext1-otext6` parameters. When the protocol is COPS and resync mode is AUTO, the `itext` and `otext1-otext6` values represent characters that trigger the protocol analyzer's drop sync operation.

The `itext` parameter is an 8-bit value that tells the data link control hardware what character to drop sync on while in the transparent text mode. See `set_transtext()` for more information on the transparent text mode.

The `otext` parameters (`otext1 - otext6`) form an array of six 8-bit values defining characters that the data link control hardware drops sync on while outside of the transparent text mode.

Return Values:

SUCCESSFUL (0)

ERROR_1 (-1)	The protocol is not COPS.
ERROR_2 (-2)	The mode is not AUTO.

See Also:

`get_resyncafter(), get_resyncmode(), resync(), set_resync(), set_protocol()`

Example:

```
#include <dlib.include>
#include <retval.include>

main()
{
   char itext, otext1, otext2, otext3, otext4, otext5, otext6;
   int result;

   if((result =
      get_resynchars(&itext,&otext1,&otext2,&otext3,&otext4,&otext5,&otext6))
      != SUCCESSFUL )
   {
      printf("Error #%d returned from get_resynchars().\n",result);
      exit();
   }
   printf("The 4954 will start to resync after '%c' in the frame or\n",itext);
   printf("one of the following values outside the frame:\n");
   printf("     '%c',\n     '%c',\n     '%c',\n     '%c',\n     '%c',\n     '%c'\n",
         otext1, otext2, otext3, otext4, otext5, otext6);
   getch();
}
```

get_resyncmode( )

Format:

```
#include <dlib.include>
#include <retval.include>

int get_resyncmode(rmode)
int *rmode;
```

Description:

Puts the currently selected resync mode value into the memory location pointed to by the rmode parameter. This function should only be used when a character-oriented protocol (COPS in set_protocol() or Char Asyn/Syn in the Setup Menu) is selected and the mode is synchronous (SYNC_DCE or SYNC_DTE in set_protocol() or Sync in the Setup Menu). The following resync mode values are located in the dlib.include file:

rmode	value
MANUAL	0x1
AUTO	0x2

The resync mode values can be modified using set_resync() or the protocol analyzer's Setup Menu. The get_resyncmode function may be called while the data link control hardware is running.

Return Values:

SUCCESSFUL (0)

ERROR_1 (-1) The protocol is not COPS.

ERROR_2 (-2) The mode is not SYNC_DCE or SYNC_DTE.

See Also:

get_resyncafter(), get_resynchars(), resync(), set_resync(), set_protocol()

Example:

```
#include <dlib.include>
#include <retval.include>

main()
{
    unsigned int rmode;
    int result;

    if((result = get_resyncmode(&rmode)) != SUCCESSFUL)
    {
        printf("Error #%d returned from get_resyncmode().\n", result);
        getch();
        exit();
    }

switch(rmode)
    {
        case MANUAL:
            printf("The 4954 is set to resync manually.");
            break;
        case AUTO:
            printf("The 4954 is set to resync automatically.");
            break;
        default:
            printf("The value of the resynchronization mode is %d.",rmode);
    }
    getch();
}
```

get_startbcc( )

Format:

```
#include <dlib.include>
#include <retval.include>

int get_startbcc(startbcc1,startbcc2)
char *startbcc1, *startbcc2;
```

Description:

Puts the currently selected startbcc characters into the memory locations pointed to by the `startbcc1` and `startbcc2` parameters. These parameters are used to start the block check character error-check calculations.

This function should only be used when a character-oriented protocol (`COPS` in `set_protocol()` or `Char Asyn/Syn` in the Setup Menu) is selected and error checking is active (anything but `NO_ERROR_CHECK` in `set_protocol()` or `None` in the Setup Menu).

The startbcc values may be modified using `set_bcc()` or the protocol analyzer's Setup Menu. The get_startbcc function may be called while the data link control hardware is running.

Return Values:

`SUCCESSFUL (0)`

`ERROR_1 (-1)` The protocol is not `COPS`.

`ERROR_2 (-2)` The errorcheck is `NO_ERROR_CHECK`.

See Also:

`set_bcc(), get_stopbcc()`

Example:

```
#include <dlib.include>
#include <retval.include>

main()
{
   char startbcc1, startbcc2;
   int result;

   if((result = get_startbcc(&startbcc1, &startbcc2)) != SUCCESSFUL)
   {
      printf("Error #%d returned from get_startbcc().\n",result);
      exit();
   }
   printf("The BCC starts after either '%c' and '%c'.\n",startbcc1, startbcc2);
   getch();
}
```

get_stop_states( )

Format:

```
#include <dlib.include>          /* for ON, OFF */
#include <leads.include>      /* for ACTIVE, NOT_DRIVEN, and all lead_id defs */
#include <retval.include>

int get_stop_states(lead_id, stop_state)
long lead_id;
int *stop_state;
```

Description:

Puts the current stop state for the specified lead into the memory location pointed to by the `stop_state` parameter. The lead id values and some of the stop state values are defined in the `leads.include` file, and the remaining stop state values can be found in `dlib.include`.

stop_state	value
OFF	0x0
ON	0x1
NOT_DRIVEN	0x2
MARKING	0x3
ACTIVE	0x4

The stop state values may be modified using the `set_stop_states` function.

Return Values:

SUCCESSFUL (0)

ERROR_1 (-1) The `lead_id` parameter was invalid.

ERROR_2 (-2) The value returned for the requested `stop_state` was invalid

get_stop_states()

See Also:

```
set_stop_states()
```

Example:

```
#include <dlib.include>
#include <leads.include>
#include <retval.include>

main()
{
    int result;
    int stop_state;

    if((result = get_stop_states(RTS, &stop_state)) != SUCCESSFUL)
    {
        printf("Error #%d returned from get_stop_states().\n",result);
        exit();
    }

    switch(stop_state)
    {
        case(ON):
            printf("The RTS will be on after stop_data() is called.");
            break;
        case(OFF):
            printf("The RTS will be off after stop_data() is called.");
            break;
        case(NOT_DRIVEN):
            printf("The RTS will be not driven after stop_data() is called.");
            break;
    }
    getch();
}
```

get_stopbcc( )

Format:

```
#include <dlib.include>
#include <retval.include>

int get_stopbcc(stopbcc1, stopbcc2)
char *stopbcc1, *stopbcc2;
```

Description:

Puts the currently selected stopbcc characters into the memory locations pointed to by the `stopbcc1` and `stopbcc2` parameters. These parameters are used to stop the block check character error-check calculations.

This function should only be used when a character-oriented protocol (COPS in `set_protocol()` or **Char Asyn/Syn** in the Setup Menu) is selected and error checking is active (anything but `NO_ERROR_CHECK` in `set_protocol()` or **None** in the Setup Menu).

The stopbcc values may be modified using `set_bcc()` or the protocol analyzer's Setup Menu. The get_stopbcc function may be called while the data link control hardware is running.

Return Values:

`SUCCESSFUL (0)`

`ERROR_1 (-1)`	The protocol is not COPS.
`ERROR_2 (-2)`	The errorcheck is `NO_ERROR_CHECK`.

See Also:

`set_bcc(), get_startbcc()`

get_stopbcc( )

Example:

```
#include <dlib.include>
#include <retval.include>

main()
{
   char stopbcc1, stopbcc2;
   int result;

   if((result = get_stopbcc(&stopbcc1, &stopbcc2)) != SUCCESSFUL)
   {
      printf("Error #%d returned from get_stopbcc().\n",result);
      exit();
   }

   printf("The stop BCC characters are %x and %x.\n",stopbcc1, stopbcc2);
   getch();
}
```

get_synchars( )

Format:

```
#include <dlib.include>
#include <retval.include>

int get_synchars(mode, synchar1, synchar2)
int *mode;
char *synchar1, *synchar2;
```

Description:

Puts the currently selected sync chars into the memory locations pointed to by the synchar1 and synchar2 parameters. The value of the current synchronization mode is placed in the memory location pointed to by the mode parameter. This function should only be used when a character-oriented protocol (COPS in set_protocol() or Char Asyn/Syn in the Setup Menu) is selected and the mode is synchronous (SYNC_DCE or SYNC_DTE in set_protocol() or Sync in the Setup Menu).

The synchar values may be modified using set_sync() or the protocol analyzer's Setup Menu. The get_synchars function may be called while the data link control hardware is running.

Return Values:

SUCCESSFUL (0)

ERROR_1 (-1) The protocol is not COPS.

ERROR_2 (-2) The mode is not synchronous (must be either SYNC_DCE or SYNC_DTE).

See Also:

set_sync()

Example:

```
#include <dlib.include>
#include <retval.include>

main()
{
    int mode;
    char synchar1, synchar2;
    int result;

    if((result = get_synchars(&mode,&synchar1,&synchar2)) != SUCCESSFUL)
    {
        printf("Error #%d returned from get_synchars().\n",result);
        exit();
    }
    printf("The sync characters are %x(hex) and %x(hex), for mode %d.\n"
        ,synchar1, synchar2,mode);
    getch();
}
```

get_time()

Format:

```
#include <time.include>
#include <retval.include>

void get_time()
struct tm *time;
```

Description:

Captures the current system time from the real-time-clock and writes it to the data structure pointed to by the `time` parameter. The `tm` data structure is defined in the `time.include` file (see chapter 4, "Include Files", for more information), and is outlined below.

struct tm

Type	Field	Description
int	tm_msecs	0-900 milliseconds after the second (100 msec intervals)
int	tm_sec	0-59 seconds after the minute
int	tm_min	0-59 minutes after the hour
int	tm_hour	0-23 hours after midnight
int	tm_day	1-31 days of the month
int	tm_mon	1-12 months of the year
int	tm_year	0-99 years after turn of century

Return Values:

None

get_time()

See Also:

set_time()

Example:

```
#include <time.include>

main()
{
    struct tm time;

    get_time(&time);
    printf("The date is %d/%d/%d and the time is %d:%d:%d.%d.",
        time.tm_mon,
        time.tm_day,
        time.tm_year,
        time.tm_hour,
        time.tm_min,
        time.tm_sec,
        time.tm_msecs );
    getch();
}
```

get_transtext()

Format:

```
#include <dlib.include>
#include <retval.include>

int get_transtext(mode,ttextchar)
int *trans_mode;
char *ttextchar;
```

Description:

Puts the currently selected transparent text character into the memory location pointed to by the `ttextchar` parameter. The `trans_mode` parameter gets the current value of the transparent text mode, which may be either `ON` (1) or `OFF` (0).

The transparent text character, `ttextchar`, is an 8-bit value that defines the boundaries of the transparent text mode. It signals both the beginning and the end of the transparent text mode. While transparent text mode is active (`trans_mode` is `ON`), all control characters are treated as data, that is, their defined control functions are not executed.

Return Values:

`SUCCESSFUL (0)`

`ERROR_1 (-1)` The `protocol` is not `COPS`.

See Also:

`set_transtext()`

Library Functions

Example:

```
#include <dlib.include>
#include <retval.include>

main()
{
    int mode;
    char transtext;
    int result;

    if((result = get_transtext(&mode,&transtext)) != SUCCESSFUL)
    {
        printf("Error #%d returned from get_transtext().\n",result);
        exit();
    }
    printf("The transparent text character is '%c', mode = %d\n",transtext,mode);
    getch();
}
```

getc( ), getchar( )

Format:

```
#include <stdio.include>

int getc(file)
FILE *file;

int getchar()
```

Description:

Reads a character from a file or input stream. The `getc` function looks for input from whatever file or stream was specified by `file`, while `getchar()`, a macro found in the `stdio.include` file, takes its input only from the standard input stream.

As a character is read, `getc()` and `getchar()` lock the keyboard so that no other process can gain access to it. In this way, a process is prevented from collecting information that was not intended for it. The keyboard can also be locked by calling `keyboard_lock()`.

A process that attempts to read from the keyboard when it has already been locked is blocked until the process that locked the keyboard releases it by calling `keyboard_unlock()`, or by terminating itself.

The keyboard functions that lock the keyboard are: `fscanf()`, `fgets()`, `getc()`, `getch()`, `getchar()`, `gets()`, `is_key_avail()`, `scanf()`, and `ungetch()`.

Return Values:

Returns the character read from the file or input stream.

See Also:

```
getch()
```

Example:

```
#include <stdio.include>

main()
{
   int ch;

   printf("Press a key, then press RETURN:\n");
   ch = getc(stdin);
   printf("The value of the key pressed is: %d.\n",ch);
   getch();
}
```

getch( )

Format:

```
#include <conio.include>

int getch()
```

Description:

Reads an unbuffered character from the keyboard without echoing the key to the screen. As it reads a character, `getch()` locks the keyboard so that no other process can gain access to it. In this way, a process is prevented from collecting information that was not intended for it. The keyboard can also be locked by calling `keyboard_lock()`.

A process that attempts to read from the keyboard when it has already been locked is blocked until the process that locked the keyboard releases it by calling `keyboard_unlock()`, or by terminating itself.

The keyboard functions that lock the keyboard are: `fscanf()`, `fgets()`, `getc()`, `getch()`, `getchar()`, `gets()`, `is_key_avail()`, `scanf()`, and `ungetch()`.

Return Values:

Returns the character read from the keyboard.

See Also:

`getc()`, `ungetch()`

Example:

```
#include <conio.include>

main()
{
   int ch;

   while((ch = getch()) != CLEAR_DISPLAY) /* CLEAR_DISPLAY is in conio.include */
      printf("The value of the key pressed is: %d.\n",ch);
}
```

gets()

Format:

```
char *gets(buffer)
char *buffer;
```

Description:

Reads a character string from the standard input stream, stdin, and places it in the buffer pointed to by `buffer`. The input string consists of all characters received up to and including the first newline character (`'\n'`). The `gets` function replaces the newline character with a null character (`'\0'`) which is placed in the buffer. `fgets()`, on the other hand, retains the newline character and stores it in `buffer`.

As a character string is read, `gets()` locks the keyboard so that no other process can gain access to it. In this way, a process is prevented from collecting information that was not intended for it. The keyboard can also be locked by calling `keyboard_lock()`.

A process that attempts to read from the keyboard when it has already been locked is blocked until the process that locked the keyboard releases it by calling `keyboard_unlock()`, or by terminating itself.

The keyboard functions that lock the keyboard are: `fscanf()`, `fgets()`, `getc()`, `getch()`, `getchar()`, `gets()`, `is_key_avail()`, `scanf()`, and `ungetch()`.

Return Values:

Returns a pointer to the string read from the keyboard, or a `NULL` pointer if an error occurred.

See Also:

`fgets()`, `puts()`, `getch()`

Example:

```
main()
{
   char instr[70];

   gets(instr);
   printf("The string read from stdin is %s.", instr);
   getch();
}
```

hold_event( )

Format:

```
#include <message.include>
#include <retval.include>

int hold_event(event)
void *event;
```

Description:

Retains access to the event specified by the `event` parameter even after sending it to another process (see `send_message()`). This is accomplished by incrementing the `held_count` parameter of the specified event.

Return Values:

`SUCCESSFUL (0)`

`ERROR_1 (-1)` Event not found

See Also:

`read_message(), send_message(), release_event()`

Library Functions

Example:

```
#include <dlib.include>
#include <retval.include>
#include <message.include>

main()
{
    MESSAGE message;
    int message_counter = 0;

    start_data();

    while(1)
    {
        if(read_message(&message,WAIT,WAIT_FOREVER))
            printf("Error reading queue.\n");
        else
        {
            message_counter += 1;
            printf("message #%d read.\n",message_counter);
            if ( message_counter == 10 )
                hold_event(message.body.event.event_ptr);
            else
                release_event(message.body.event.event.ptr);
        }
    }
}
```

init_rs232( )

Format:

```
void init_rs232()
```

Description:

Initializes the protocol analyzer's serial port. This function must be called prior to calling `print_char()` or any of the other RS232 functions.

Return Values:

None

See Also:

```
rs232_write_ready(), rs232_read_ready(), read_rs232(), write_rs232(), print_char()
```

Example:

```
main()
{
    init_rs232();

    printf("the rs232 port is now initialized!\n");
    getch();
}
```

Library Functions

init_trigger( )

Format:

```
int init_trigger(message_type, number_of_subtypes, subtype_args)
unsigned message_type;
unsigned number_of_subtypes;
unsigned subtype_args;
```

Description:

Initializes the system trigger_on_message function to trigger on a message of type message_type with a subtype that is one of the subtypes in the argument list subtype_args. The number_of_subtypes parameter represents the number of subtypes that follow in the subtype_args list. Individual subtype values can range from 1 to 31.

If the number_of_subtypes parameter is zero, init_trigger() clears all subtype triggers that were set for the specified message_type. If the number_of_subtypes parameter is greater than 31, the init_trigger function sets all subtypes (of a certain message_type) to triggers. In these two cases, init_trigger() ignores any subtypes listed in subtype_args.

Return Values:

Returns the number of new subtype triggers set by the call to init_trigger().

See Also:

trigger_on_message()

init_trigger( )

Example:

```
#include <message.include>
#define The_sun_sets_in_the_west 1

main()
{
   MESSAGE message;
   int number_set;

   number_set = init_trigger(DATACOMM, 2 , DTE_FRAME, END_OF_DISC_RUN);
   printf("There are %d subtypes set by init_trigger for DATACOMM events.\n",
                                                                  number_set);
   number_set = init_trigger(TIMER, 32);
   printf("There are %d subtypes set by init_trigger for timer messages.\n",number_set);
   set_timer(10L);  /* timeout after 1 second */
   start_data(); /* start receiving DATACOMM events */

   while(The_sun_sets_in_the_west)
      switch(trigger_on_message(&message))
      {
         case DATACOMM:
            printf("Process DATACOMM messages here.\n");
            break;
         case TIMER:
            printf("Process TIMER messages here.\n");
            break;
         default: /* must be an error subtype */
            printf("Process ERROR messages here.\n");
      }
   getch();
}
```

is_key_avail()

Format:

```
int is_key_avail();
```

Description:

Polls the keyboard buffer for available keys. This function locks the keyboard when called (if the keyboard isn't already locked), so that unless keyboard_unlock() is called directly, or the process terminates, no other process can gain access to the keyboard after is_key_available() has been called. If another process has gained control of the keyboard, however, is_key_available does not wait for the keyboard to be released; it returns without blocking.

Return Values:

Returns the number of keys pressed.

See Also:

getch(), keyboard_lock(), keyboard_unlock()

Example:

```
main()
{
    int ch;

    while( !is_key_avail() )
        printf("Waiting for a keystroke.\n");
    ch = getch();
    printf("The hex value of the key pressed is %x.\n",ch);
    getch();
}
```

Library Functions

is_msg_avail()

Format:

```
int is_msg_avail();
```

Description:

Polls the process message queue for an available message.

Return Values:

Returns the number of messages available in the queue.

See Also:

```
read_message(), send_message()
```

Example:

```
#include <dlib.include>
#include <retval.include>
#include <message.include>

main()
{
   MESSAGE message;
   int message_counter = 0;

   start_data();

   while(!is_msg_avail())  /* wait until a msg is available */
      printf("Waiting for a message.\n");

   if(read_message(&message,WAIT,WAIT_FOREVER))
      printf("Error reading queue.\n");
   else
   {
      printf("message read type/subtype fields are %d/%d .\n",
         message.type, message.subtype);
      release_event(message.body.event.event_ptr);
   }
   getch();
}
```

isalnum( )

Format:

```
#include <ctype.include>

int isalnum(ch)
int ch;
```

Description:

Tests for an alphanumeric character ('A' through 'Z', 'a' through 'z', or '0' through '9'). The `isalnum` macro expects 8 bit values as input.

Return Values:

Returns an integer greater than zero if `ch` is an alphanumeric character, zero if it is not.

See Also:

`isalpha(), isascii(), iscntrl(), isdigit(), isgraph(), islower(), isprint(), ispunct(), isspace,(), isupper(), isxdigit(), toascii(), tolower(), toupper()`

Example:

```
#include <ctype.include>
#include <stdio.include>

main()
{
   int ch;

   printf("Press a key, then press RETURN. Press any key to exit.");
   while((ch = getc(stdin)) != '\n')
   {
```

```
      puts("****************************************************");
      if(isalnum(ch))
         printf("The character '%c' is alphanumeric.\n",ch);
      if(isalpha(ch))
         printf("The character '%c' is alphabetic.\n",ch);
      if(isascii(ch))
         printf("The character '%c' is an ASCII character.\n",ch);
      if(iscntrl(ch))
         printf("The character '%c' is a control character.\n",ch);
      if(isdigit(ch))
         printf("The character '%c' is a numeric digit.\n",ch);
      if(isgraph(ch))
         printf("The character '%c' is a graphics character.\n",ch);
      if(islower(ch))
         printf("The character '%c' is in lower case.\n",ch);
      if(isprint(ch))
         printf("The character '%c' is a printable character.\n",ch);
      if(ispunct(ch))
         printf("The character '%c' is a punctuation character.\n",ch);
      if(isspace(ch))
         printf("The character '%c' is a white space character.\n",ch);
      if(isupper(ch))
         printf("The character '%c' is in upper case.\n",ch);
      if(isxdigit(ch))
         printf("The character '%c' is a hex digit.\n",ch);
   }
   getch();
}
```

isalpha( )

Format:

```
#include <ctype.include>

int isalpha(ch)
int ch;
```

Description:

Tests for an alphabetic character ('A' through 'Z', or 'a' through 'z'). The `isalpha` macro expects 8 bit values as input.

Return Values:

Returns an integer greater than zero if `ch` is an alphabetic character, zero if it is not.

See Also:

`isalnum(), isascii(), iscntrl(), isdigit(), isgraph(), islower(), isprint(), ispunct(), isspace,(), isupper(), isxdigit(), toascii(), tolower(), toupper()`

Example:

See the example in `isalnum()`.

isascii( )

Format:

```
#include <ctype.include>

int isascii(ch)
int ch;
```

Description:

Tests for an ASCII character (0x00 through 0x7F). The isascii macro expects 8 bit values as input.

Return Values:

Returns an integer greater than zero if ch is an ASCII character, zero if it is not.

See Also:

isalnum(), isalpha(), iscntrl(), isdigit(), isgraph(), islower(), isprint(), ispunct(), isspace,(), isupper(), isxdigit(), toascii(), tolower(), toupper()

Example:

See the example in isalnum().

iscntrl( )

Format:

```
#include <ctype.include>

int iscntrl(ch)
int ch;
```

Description:

Tests for a control character (0x00 through 0x1F, as well as 0x7F). The iscntrl macro expects 8 bit values as input.

Return Values:

Returns an integer greater than zero if ch is a control character, zero if it is not.

See Also:

isalnum(), isalpha(), isascii(), isdigit(), isgraph(), islower(), isprint(), ispunct(), isspace,(), isupper(), isxdigit(), toascii(), tolower(), toupper()

Example:

See the example in isalnum().

Library Functions

isdigit( )

Format:

```
#include <ctype.include>

int isdigit(ch)
int ch;
```

Description:

Tests for a numeric digit ('0' through '9'). The `isdigit` macro expects 8 bit values as input.

Return Values:

Returns an integer greater than zero if `ch` is a numeric digit, zero if it is not.

See Also:

`isalnum(), isalpha(), isascii(), iscntrl(), isgraph(), islower(), isprint(), ispunct(), isspace,(), isupper(), isxdigit(), toascii(), tolower(), toupper()`

Example:

See the example in `isalnum()`.

isgraph( )

Format:

```
#include <ctype.include>

int isgraph(ch)
int ch;
```

Description:

Tests for a printable character excluding the space character (0x21 through 0x7E). The isgraph macro expects 8 bit values as input.

Return Values:

Returns an integer greater than zero if ch is a graphic character, zero if it is not.

See Also:

isalnum(), isalpha(), isascii(), iscntrl(), isdigit(), islower(), isprint(), ispunct(), isspace,(), isupper(), isxdigit(), toascii(), tolower(), toupper()

Example:

See the example in isalnum().

islower( )

Format:

```
#include <ctype.include>

int islower(ch)
int ch;
```

Description:

Tests for a lowercase character ('a' through 'z'). The `islower` macro expects 8 bit values as input.

Return Values:

Returns an integer greater than zero if `ch` is a lowercase character, zero if it is not.

See Also:

```
isalnum(), isalpha(), isascii(), iscntrl(), isdigit(), isgraph(), isprint(), ispunct(),
isspace,(), isupper(), isxdigit(), toascii(), tolower(), toupper()
```

Example:

See the example in `isalnum()`.

isprint( )

Format:

```
#include <ctype.include>

int isprint(ch)
int ch;
```

Description:

Tests for a printable character (0x20 through 0x7E). The isprint macro expects 8 bit values as input.

Return Values:

Returns an integer greater than zero if ch is a printable character, zero if it is not.

See Also:

isalnum(), isalpha(), isascii(), iscntrl(), isdigit(), isgraph(), islower(), ispunct(), isspace,(), isupper(), isxdigit(), toascii(), tolower(), toupper()

Example:

See the example in isalnum().

ispunct( )

Format:

```
#include <ctype.include>

int ispunct(ch)
int ch;
```

Description:

Tests for a punctuation character (0x21 through 0x2F, 0x3A through 0x40, 0x5B through 0x60, or 0x7B through 0x7E). The ispunct macro expects 8 bit values as input.

Return Values:

Returns an integer greater than zero if ch is a punctuation character, zero if it is not.

See Also:

isalnum(), isalpha(), isascii(), iscntrl(), isdigit(), isgraph(), islower(), isprint(), isspace,(), isupper(), isxdigit(), toascii(), tolower(), toupper()

Example:

See the example in isalnum().

isspace( )

Format:

```
#include <ctype.include>

int isspace(ch)
int ch;
```

Description:

Tests for a white space character (0x09 through 0x0D, or 0x20). The isspace macro expects 8 bit values as input.

Return Values:

Returns an integer greater than zero if ch is a white space character, zero if it is not.

See Also:

isalnum(), isalpha(), isascii(), iscntrl(), isdigit(), isgraph(), islower(), isprint(), ispunct(), isupper(), isxdigit(), toascii(), tolower(), toupper()

Example:

See the example in isalnum().

isupper()

Format:

```
#include <ctype.include>

int isupper(ch)
int ch;
```

Description:

Tests for a uppercase character ('A' through 'Z'). The isupper macro expects 8 bit values as input.

Return Values:

Returns an integer greater than zero if ch is a uppercase character, zero if it is not.

See Also:

isalnum(), isalpha(), isascii(), iscntrl(), isdigit(), isgraph(), islower(), isprint(), ispunct(), isspace,(), isxdigit(), toascii(), tolower(), toupper()

Example:

See the example in isalnum().

isxdigit( )

Format:

```
#include <ctype.include>

int isxdigit(ch)
int ch;
```

Description:

Tests for a hexadecimal digit ('A' through 'F', 'a' through 'f', or '0' through '9'). The `isxdigit` macro expects 8 bit values as input.

Return Values:

Returns an integer greater than zero if `ch` is a hexadecimal digit, zero if it is not.

See Also:

`isalnum(), isalpha(), isascii(), iscntrl(), isdigit(), isgraph(), islower(), isprint(), ispunct(), isspace,(), isupper(), toascii(), tolower(), toupper()`

Example:

See the example in `isalnum()`.

itoa( )

Format:

```
#include <stdlib.include>

char *itoa (num,str,radix)

int num;
char *str;
int radix;
```

Description:

Converts the value of num to a null-terminated character string of digits and stores the result in the memory location pointed to by the str parameter. The radix parameter specifies the base of the argument to be converted.

Return Values:

Returns address of str.

See Also:

atoi(), ftoa() ltoa()

itoa()

Example:

```
#include <stdlib.include>

main()
{
   int i = 20;
   char str[10];

   itoa(i,str,16);
   printf("The base 16 representation of %d is %s.\n",i,str);
   getch();
}
```

keyboard_lock()

Format:

```
void keyboard_lock()
```

Description:

Locks the keyboard for exclusive use by the current process. If the keyboard has been locked by another process prior to the function call, the current calling process is blocked until it can lock the keyboard.

Several general I/O functions, `is_key_avail()`, `getch()`, `gets()`, `getc()`, `getchar()`, `scanf()` and `ungetch()` call this function indirectly and block other processes from keyboard access. `fgets()`, `fgetc()`, `fscanf()` and `fread()` call `keyboard_lock()` when the file pointer is `stdin`; `read()` locks the keyboard when its file descriptor is zero. In each of these cases, the keyboard is locked until `keyboard_unlock()` is called or until the calling process terminates.

Return Values:

None

See Also:

```
keyboard_unlock()
```

keyboard_lock()

Example:

```
main()
{
   keyboard_lock();
   printf("The keyboard is now locked for this process - press a key.\n");
   getch();
   keyboard_unlock();
   printf("The keyboard is not locked for this process.\n");
   wait(30l);
}
```

Library Functions

keyboard_unlock( )

Format:

```
int keyboard_unlock()
```

Description:

If called by the process that locked the keyboard, allows another process to take control of the keyboard. If another process had called `keyboard_lock()`, and was blocked, it is unblocked.

Return Values:

Returns a `1` if the process successfully unlocked the keyboard.

See Also:

`keyboard_lock()`

Example:

See the example in `keyboard_lock()`.

Library Functions

log()

Format:

```
#include <math.include>

double log(x)
double x;
```

Description:

Returns the natural logarithm of x.

Return Values:

Returns the result of the log function.

See Also:

```
log10()
```

Example:

```
#include <math.include>

main()
{
    double x = 10,y;

    y = log(x);
    printf("The log of %f is %f.",x,y);
    getch();
}
```

log10( )

Format:

```
#include <math.include>

double log10(x)
double x;
```

Description:

Returns the base 10 log of x.

Return Values:

Returns the result of the `log10` function.

See Also:

```
log()
```

Example:

```
#include <math.include>

main()
{
   double x = 10,y;

   y = log10(x);
   printf("The log (base 10) of %f is %f.",x,y);
   getch();
}
```

longjmp( )

Format:

```
#include <setjmp.include>

void longjmp(env, val)
jmp_buf env;
int val;
```

Description:

Restores the stack environment values (env) previously saved by a call to setjmp(), and causes program execution to continue as if the call to setjmp() was just terminating with val as its return code. The val parameter must be a nonzero number. The longjmp and setjmp functions are useful for dealing with errors encountered by the low-level functions of a program.

The longjmp function must not be called unless env has already been initialized by a call to setjmp(). It also must not be called if the function that called setjmp() has returned.

Return Values:

None

See Also:

setjmp()

Example:

```
#include <setjmp.include>

main()
{
   jmp_buf buff;

   printf("We are about to call setjmp.\n");
   printf("Please hit any character to call it.\n");
   getch();
   if(setjmp(buff))
   {
      printf("We are in the if clause.\n");
      printf("We should have had an error and will return.\n");
   }
   else
   {
      printf("We are executing the else clause.\n");
      printf("We are now pretending to have an error.\n");
      printf("Hit any key to have a fake error and call longjmp.\n");
      getch();
      longjmp(buff,-1);
      printf("We have just called longjmp.  This should never get printed.\n");
   }
   printf("Please hit any key to return.\n");
   getch();
}
```

lseek( )

Format:

```
#include <stdio.include>

long lseek(fdesc, offset, origin)
int fdesc;
long offset;
int origin;
```

Description:

Moves the file pointer `fdesc` to a location in the file `offset` bytes from the `origin`. The `fdesc` parameter must be the file descriptor returned by `open()`. Constant values for the `origin` parameter are defined in the `stdio.include` file, and are described below:

origin	Description
SEEK_SET	The file pointer indicates the beginning of the file.
SEEK_CUR	The file pointer indicates the current position in the file.
SEEK_END	The file pointer indicates the end of the file.

Return Values:

Returns zero if the function was successful, or -1 if an error occurred during the operation.

See Also:

`fseek(), open(), close()`

Example:

```
#include <stdio.include>
#include <fcntl.include>

main()
{
    int fdesc;
    long seek_result, write_result;
    char instr[20];

    if((fdesc = open("file1.text",O_WRONLY|O_CREAT)) == -1)
       printf("Can't create file1.text.");
    else
    {
       if(write_result = write(fdesc,"hello world\n",12) != 12)
          printf("Write error detected.");
       else
       {
          close(fdesc);
          if((fdesc = open("file1.text",O_RDONLY)) == -1)
             printf("Can't open file1.text.");
          else if ((seek_result = lseek(fdesc,6L,SEEK_SET)) != 6L)
             printf("Seek error detected.");
          else
          {
             read(fdesc,instr,3);
             close(fdesc);
             instr[3] = 0;
             printf("the string read after lseek is %s.",instr);
          }
       }
    }
    getch();
}
```

ltoa( )

Format:

```
#include <stdlib.include>

char *ltoa(num,str,radix)

long num;
char *str;
int radix;
```

Description:

Converts the digits in `num` to a null terminated character string and stores the result in the memory space pointed to by the `str` parameter. The `radix` parameter specifies the base of the argument to be converted. Returns the address of `str`.

Return Values:

Returns the address of `str`. There is no error return value.

See Also:

`atol(), itoa()`

Example:

```
#include <stdlib.include>

main()
{
   long i = 20;
   char str[10];

   ltoa(i,str,16);
   printf("The base 16 representation of %ld is %s.\n",i,str);
   getch();
}
```

make_file()

Format:

```
make_file(pathname, size)
char *pathname;
unsigned long size;
```

Description:

Creates a file, using the value of the `size` parameter as the length of the new file. The `pathname` parameter must contain the full device/directory/filename path.

Return Values:

0	The file was created successfully.
1	An error occurred during the operation.

See also:

`unlink()`

Library Functions

Example:

```
main()
{
   if(make_file("c:makefile.text",2048L))
      printf("Error creating file c:makefile.text.\n");
   else
      printf("Created file:  c:makefile.text; size:  2048 bytes");
   getch();
}
```

makedir( )

Format:

```
char *makedir(rtnpath, dev, path, filename, filetype)
char rtnpath[82];
char dev;
char *path;
char *filename;
char *filetype;
```

Description:

Creates a string representing a directory path by combining the `dev`, `path`, `filename` and `filetype` parameters. The function expects to have the device supplied as a single character (for example, `'c'`), and the path, file name and file extension as a character arrays. The makedir function puts the directory path string into the memory location indicated by the `rtnpath` parameter.

The `makedir` function is useful for assembling path strings that may be used in `ch_dir()`, `fopen()`, `open()`, or other file-oriented functions. If the `dev` or `path` parameters are replaced with `NULL` characters, values from the current directory are substituted, so that only the file name and extension are changed. The current directory may be changed with `ch_dir()`.

Return Values:

Returns a pointer to the newly created directory path string.

See Also:

```
get_dir(), parsedir()
```

Library Functions

makedir( )

Example:

```
main()
{
    char rtnpath[82];

    makedir(rtnpath,'c',"c:/","makefile","text");
    printf("The string returned from makedir is %s.\n",rtnpath);
    getch();
}
```

malloc( )

Format:

```
#include <stdlib.include>

char *malloc(size)
unsigned int size;
```

Description:

Allocates `size` bytes of memory. The allocated block (`size`) cannot exceed 32K bytes.

Return Values:

Returns a pointer to the allocated memory or `NULL` if the memory cannot be allocated. When memory allocated in this way is no longer being used, it should be returned to the system by calling `free()`.

See Also:

```
calloc(), free()
```

malloc( )

Example:

```
#include <stdlib.include>
#include <stdio.include>

main()
{

    char *str, *new_str;

    str="hello world";
    if((new_str = malloc(strlen(str) + 1))!= NULL)
    {
        strcpy(new_str, str);
        printf("The new_str is %s.", new_str);
    }
    getch();
}
```

open( )

Format:

```
#include <stdio.include>
#include <fcntl.include>

int open(filename, access_mode)
char *filename;
int access_mode;
```

Description:

Opens the file whose name is a string pointed to by the `filename` parameter, using the `access_mode` parameter to determine the type of file access allowed. Values for the `access_mode` parameter are located in the `fcntl.include` file. These values, represented here by their associated names, may be joined together with the aritmetic OR operator (|), but since there is no default, one of the values given must be either `O_RDONLY`, `O_WRONLY`, or `O_RDWR`. These three values are also mutually exclusive; only one of them may be selected during a file access.

access_mode	Description
O_RDONLY	The file is opened in read-only mode.
O_WRONLY	The file is opened in write-only mode.
O_RDWR	The file is opened in read/write mode.

Library Functions

open()

access_mode	Description
O_CREAT	Creates a new file. This has no effect if the file specified by filename already exists.
O_EXCL	Causes O_CREAT to return an error message if the specified path already exists. Use only with O_CREAT.
O_TRUNC	Truncates an existing file to zero length. The file must be opened in write-only or read/write mode. File contents are destroyed.
O_APPEND	Moves the file pointer to the end of the file before every write operation.

Note The O_TRUNC access_mode option destroys all information in an existing file; it should be used with extreme caution.

Regardless of the access mode used, an existing file is not allowed to grow beyond the physical size allocated to it when it was created. If open() is used to create a file, the file size cannot be specified, but if the file is created with make_file(), a file size can be specified. Any file, therefore, that might be added on to in the future should be created with make_file().

Return Values:

Returns a file descriptor, an integer that represents the file, when successful, or -1 if the file could not be opened.

See Also:

close(), fopen(), make_file()

Example:

```
#include <stdio.include>
#include <fcntl.include>

main()
{
    int fdesc;
    long seek_result, write_result;
    char instr[20];

    if((fdesc = open("file1.text",O_WRONLY)) == -1)
        printf("Can't open file1.text.");
    else
    {
        if((write_result = write(fdesc,"hello world\n",12)) != 12)
            printf("Write error detected.");
        close(fdesc);
    }
getch();
}
```

parsedir( )

Format:

```
void parsedir(name, dev, path, filename, filetype)
char *name;
char dev[3];
char path[56];
char filename[11];
char filetype[14];
```

Description:

Breaks the path supplied by `name` into its components. The function reads in the character array, `name` (up to 82 characters long) and puts the individual pieces into `dev` (for example, `'a:'` or `'c:'`), `path`, `filename` and `filetype` (for example, `.text`, `.backup`). All of these parameters are represented by character arrays.

If the `name` parameter does not include a device or directory path, the associated parameter or parameters (`dev`, `path`) are supplied with values taken from the current path.

Return Values:

None

See Also:

`makedir()`, `get_dir()`

Library Functions

Example:

```
main()
{
    char name[82];
    char dev[3];
    char path[56];
    char filename[11];
    char type[14];

    parsedir("c:C/User/Csource/Prog1.csource", dev,path,filename,type);
    printf("The components of the full path follow:\n");
    printf("  The device is: %s.\n",dev);
    printf("    The path is: %s.\n",path);
    printf("The filename is: %s.\n",filename);
    printf("    The type is: %s.\n",type);
    getch();
}
```

pow()

Format:

```
#include <math.include>

double pow(x, y)
double x, y;
```

Description:

Raises x to the power of y.

Return Values:

Returns the result of the operation.

Library Functions

See Also:

```
exp()
```

Example:

```
#include <math.include>

main()
{
    double x = 10,y = 3,powx;

    powx = pow(x,y);
    printf("The value of %f raised to the power of %f is %f.",x,y,powx);
    getch();
}
```

print_char()

Format:

```
void print_char(chr)
char chr;
```

Description:

Prints the given character to the RS232 port. This function should only be used after `init_rs232()` has been called.

Return Values:

None

See Also:

`init_rs232(), rs232_write_ready(), write_rs232()`

Example:

```
#include <stdio.include>

main()
{
   int ch = 0;

   init_rs232();
   printf("Type text to send to printer and press RETURN - enter \"*\" to exit\n\n");
   while((ch = getc(stdin)) != '*')
      print_char(ch);
}
```

printf( )

Format:

```
void printf(format,args)
char *format;
char *args;
```

Description:

Outputs arguments in `args` to the standard output device, `stdout`, according to `format`.

The character string pointed at by `format` directs the output operation, and contains two types of information: ordinary alphanumeric characters, which are output unchanged; and conversion specifications, each of which causes the conversion and output of the next argument in the `args` list.

The formatted string is output from left to right. When a conversion specification is encountered, the next (initially first) argument is output according to the conversion specification.

A conversion specification has the form:

```
%[flag][width][.precision][l]type
```

Each field enclosed in braces "[ ]" is optional and consists of a single character or number signifying a particular format option. The simplest possible conversion specification contains a percent sign (%) and a conversion character (ex: %f)

`flag`

- The converted argument is left-justified when printed (the default is right-justification).

`width`

digit string The numeric digit string specifies the field width for the conversion. If the converted value has fewer characters than `width`, enough blank (space) characters are output to make the total number of characters output equal the field width. The spaces are output before or after the value, depending on the presence or absence of the left-justification flag. If the field width digits have a leading zero, zeros are used as pad characters instead of spaces. If the converted string has more characters than the value of `width`, the string is truncated.

* The `width` parameter is supplied by the corresponding argument in the argument list (`args`). The argument must be of type `int`.

`.precision`

digit string For floating point conversions, `precision` specifies the number of digits to appear after the decimal point; for character string conversions, it specifies the maximum number of characters to be printed from a string.

* The `precision` parameter is supplied by the corresponding argument in the argument list (`args`). The argument must be of type `int`.

`l`

A conversion normally performed on an `int` is performed on a `long` (may be used with the `d`, `o` and `x` conversion characters).

printf( )

The type character format is as follows:

character	type of argument	output format
d	int	signed decimal
u	int	unsigned decimal
x	int	unsigned hexadecimal
o	int	unsigned octal
f	float or double	floating point
c	char	single character
s	string	character string
e	float or double	scientific nototation
g	uses d, f or e - whichever gives	full precision in minimum space

Return Values:

None

See Also:

```
scanf(), fprintf(), sprintf()
```

Example:

```
main()
{
    int i = 20;
    double x = 1.23;

    printf("The integer in decimal is %d, in octal is %o, in hex is %x.\n",i,i,i);
    printf("The double is %5.2f.\n",x);
    getch();
}
```

put_all_sks()

Format:

```
#include <video.include>

void put_all_sks(s1, s2, s3, s4, s5, s6, s7, s8, attribute)
char *s1, *s2, *s3, *s4, *s5, *s6, *s7, *s8;   /* softkey labels (null-terminated) */
int attribute;
```

Description:

Writes the given labels onto the corresponding softkeys by calling `put_sk()` for each softkey. The softkeys are numbered from left to right. The `attribute` parameter is used to choose the video attribute for all the softkeys. The `attribute` values may be arithmetically OR'd together to create a combination of effects.

Although `INVERSE` and `INVERSE|HALF_BRIGHT` (inverse-video OR'd with low-intensity) are the attributes best suited for softkey painting, any of the attribute values listed in the `set_attribute()` description may be used. The constant values for `attribute` are defined in the `video.include` file.

To keep an already existing softkey, insert a `NULL` (`'\0'`) character in place of its label in the argument list. The function skips over the key without overwriting it. For more information on formatting individual softkeys, see the `put_sk()` description.

Return Values:

None

See Also:

`put_sk()`

Library Functions

put_all_sks( )

Example:

```
#include <video.include>

main()
{
    put_all_sks("s_key1",
                "s_key2",
                "s_key3",
                "s_key4",
                "s_key5",
                "s_key6",
                "s_key7",
                "s_key8",INVERSE);
    getch();
}
```

put_sk()

Format:

```
#include <video.include>      /* for attribute definitions */
#include <conio.include>      /* for SK1 - SK8 definitions */

void put_sk(label, softkey_id, attribute)
char *label;
int softkey_id, attribute;
```

Description:

Writes a label onto one of the eight softkeys using the specified display attribute. The label is centered on the softkey. This is known as "painting" a softkey.

The softkey label is a null-terminated string stored in the memory location pointed to by the `label` parameter. An opening single quote character (‘ -- press Shift @ on the protocol analyzer's keyboard) is used to mark the division between the upper and lower rows of the label. If the opening single quote is omitted, the label appears on the upper row of the softkey. Each row may contain up to nine (9) characters; any additional characters are truncated.

The integer constants for the `attribute` and `softkey_id` parameters are found in `video.include` and `conio.include`, respectively. The constant values for `softkey_id` and for the `attribute` options best suited for softkey painting are shown below:

attribute
NORMAL
INVERSE
BLINK
HALF_BRIGHT

softkey_id
SK1
SK2
SK3
SK4
SK5
SK6
SK7
SK8

put_sk()

Other attribute values are shown in the set_attribute() description. The attribute options may be arithmetically "OR'd" together to create combinations of the video attributes. For example, entering INVERSE|HALF_BRIGHT as the attribute parameter creates a softkey that appears darker than a softkey created with INVERSE alone.

put_sk() returns without modifying a softkey if the label string is NULL, or if the softkey_id is not one of the SK1 through SK8 constants.

Return Values:

None

See Also:

put_all_sks()

Example:

```
#include <video.include>
#include <conio.include>

main()
{
    put_sk("This is 'S_KEY5",SK5,INVERSE|HALF_BRIGHT);
    getch();
}
```

putc( )

Format:

```
#include <stdio.include>

int putc(ch, file)
int ch;
FILE *file;
```

Description:

Writes the character ch to a file or output stream. The putc function uses the output stream specified by the file parameter.

Return Values:

Returns the character written (ch).

See Also:

```
getc(), fputc()
```

putc( )

Example:

```
#include <stdio.include>

main()
{
   char *str = "hello world";

   while(*str)
      putc(*str++,stdout);

   getch();
}
```

putch( )

Format:

```
void putch(ch)
char ch;
```

Description:

Writes the character ch to the display at the current cursor position with the current display attributes before advancing the horizontal cursor position.

Return Values:

None

See Also:

getch()

Example:

```
main()
{
    char *str = "hello world";

    while(*str)
        putch(*str++);
    getch();
}
```

puts( )

Format:

```
#include <stdio.include>

int puts(string)
char *string;
```

Description:

Writes the string pointed to by the `string` parameter to the display. `puts()` uses the current display attributes to write the string, then advances the cursor to the first column of the next line if the display is not in transparent text mode (see `set_screen_mode()`).

Return Values:

Returns the last character written, or `EOF` to indicate an error.

See Also:

```
gets()
```

Example:

```
main()
{
    puts("hello world!!!");
    getch();
}
```

Library Functions

rand( )

Format:

```
int rand()
```

Description:

Generates a positive pseudo-random number between 0 and 32767. The srand function may be used to initialize a random starting point before rand() is called.

Return Values:

Returns a pseudo-random number as described above.

See Also:

srand()

Example:

```
main()
{
    int rand_result, i;
    double frand;

    rand_result = rand();
    printf("The random number generated is %d.\n",rand_result);
    printf("The value calculated from %d for a random number\n",rand_result);
    printf("between zero and one is %f.\n",(float)((float)rand_result/(float)32767));
    getch();
}
```

This example takes any pseudo-random numbers generated by rand() and converts them to floating point numbers between 0 and 1.

read( )

Format:

```
#include <stdio.include>

int read(fdesc, buff, cnt)
int fdesc;
char *buff;
unsigned int cnt;
```

Description:

Reads cnt bytes from the file whose descriptor is fdesc and stores the information in the location indicated by the buff parameter. The fdesc parameter contains an integer "handle" that was generated by the open function when the file was first encountered in the program.

Return Values:

Returns the number of bytes actually read, which may be less than cnt if there were less than cnt bytes left in the file, zero if the read function tried to begin access at the end-of-file marker, or -1 if an error occurred during function operation.

See Also:

```
close(), open(), write()
```

Example:

```
#include <stdio.include>
#include <fcntl.include>

main()
{
    int fdesc;
    long seek_result, write_result;
    char instr[20];

    if((fdesc = open("file1.text",O_WRONLY|O_CREAT)) == -1)
        printf("Can't create file1.text.");
    else
    {
        if(write_result = write(fdesc,"hello world\n",12) != 12)
            printf("Write error detected.");
        else
        {
            if((fdesc = open("file1.text",O_RDONLY)) == -1)
                printf("Can't open file1.text.");
            else
            {
                read(fdesc,instr,5);
                instr[3] = 0;
                printf("the string read after fseek is %s.",instr);
            }
        }
        close(fdesc);
    }
    getch();
}
```

read_message()

Format:

```
#include <message.include>
#include <retval.include>

int read_message(message, wait, timeout);
MESSAGE *message;
int wait;
long timeout;
```

Description:

Reads a message from the message queue. Information from the queue is placed in the data structure pointed to by the message parameter.

Constant values for the wait parameter are defined in the message.include file. The choices are shown below:

wait	Description
WAIT	The function waits for a message for a period of timeout ticks.
NO_WAIT	The function doesn't wait for messages, and timeout is ignored.

If the wait parameter equals WAIT, read_message() blocks the calling process for up to timeout ticks (1 tick = 1/10 second) or until a message is read. If timeout equals WAIT_FOREVER (0L), the calling process is blocked until a message is read.

Return Values:

SUCCESSFUL (0)	A message was read.
NO_MESSAGE (-1)	There weren't any messages available, or read_message() timed out.

INVALID_QUEUE_NUMBER (-2)	The external variable _process_QID has been corrupted (see "Messaging and Event Buffer Services" in the *DataCommC Programming Language User's Guide* for more information).

See Also:

send_message(), is_msg_avail()

Example:

```
#include <message.include>
#include <retval.include>

main()
{
    MESSAGE message;
    int message_counter = 0;

    start_data();
    while(1)
    {
        if(read_message(&message,WAIT,WAIT_FOREVER))
            printf("Error reading queue.\n");
        else
        {
            message_counter += 1;
            printf("message #%d read.\n",message_counter);
            if(message.type == DATACOMM)
                release_event(message.body.event.event_ptr);
        }
    }
}
```

read_pod_id( )

Format:

```
int read_pod_id(pod_id)
int *pod_id;
```

Description:

Reads the pod identification from the pod connected to the data link control hardware. When the function is successful, the pod id value is placed in the memory location pointed to by the pod_id parameter. The following pod_id values are located in the dlib.include file.

pod_id	value
RS232	0x1
V_35	0x2
RS449	0x3
X_21	0x4
MIL188C	0x5
NO_POD	0x8

Library Functions

Return Values:

SUCCESSFUL (0)

ERROR_10 (-10) A fatal error occurred during an attempt to communicate with the data link control hardware

Example:

```
#include <retval.include>
#include <dlib.include>

main()
{
    int result;
    unsigned pod_id;

    if((result = read_pod_id(&pod_id)) != SUCCESSFUL)
        exit();
    switch(pod_id)
    {
        case RS232:
            printf("The 4954 is connected to an RS-232 pod.\n");
            break;
        case V_35:
            printf("The 4954 is connected to a V.35 pod.\n");
            break;
        case RS449:
            printf("The 4954 is connected to an RS-449 pod.\n");
            break;
        case X_21:
            printf("The 4954 is connected to an X.21 pod.\n");
            break;
        case MIL188C:
            printf("The 4954 is connected to a MIL-188C pod.\n");
            break;
        case NO_POD:
            printf("The 4954 is not connected to a pod.\n");
            break;
        default:
            printf("The 4954 is connected to pod type %d.\n",pod_id);
    }
    getch();
}
```

read_rs232()

Format:

```
void read_rs232(ch)
char *ch;
```

Description:

Reads a character from the RS232 port and puts it into the memory location pointed to by the `ch` parameter.

Return Values:

None

See Also:

```
init_rs232(), rs232_read_ready(), rs232_write_ready(), print_char(), write_rs232()
```

Example:

```
main()
{
   char ch = 0;

   init_rs232();
   printf("Reading from the RS232 port - press RESET to exit\n\n");
   while( ch != '*' )
      if(rs232_read_ready())
      {
         read_rs232(&ch);
         printf("The character read is '%c'.\n",ch);
      }
}
```

read_vidram()

Format:

```
#include <video.include>

void read_vidram(row, column, character, attribute)
int row, column;
int *attribute;
char *character;
```

Description:

Reads the video RAM character and attribute value at the location defined by the `row` and `column` parameters. The maximum row and column values are 25 and 80, respectively. The selected character and attribute are placed in the memory locations pointed to by the `character` and `attribute` parameters, respectively.

Return Values:

None

See Also:

```
write_vidram()
```

read_vidram()

Example:

```
#include <video.include>

main()
{
    char ch;
    int row = 1, col = 1;
    int attribute;

    printf("This is a test string.\n");
    read_vidram(row, col, &ch, &attribute);
    printf("The character at rol,col 1,1 is '%c'.\n",ch);
    printf("The character is being displayed with the following attributes:\n\n");

    if((attribute & NORMAL) == NORMAL)
        printf("       NORMAL\n");
    if((attribute & SPECIAL) == SPECIAL)
        printf("       SPECIAL\n");
    if((attribute & INVERSE) == INVERSE)
        printf("       INVERSE\n");
    if((attribute & HALF_BRIGHT) == HALF_BRIGHT)
        printf("       HALF_BRIGHT\n");
    if((attribute & BLINK) == BLINK)
        printf("       BLINK\n");

    if((attribute & NORMAL) == 0)
    {
        if(attribute & HEX_NORMAL)
            printf("       HEX_NORMAL\n");
        if(attribute &  HEX_INVERSE )
            printf("       HEX_INVERSE\n");
        if(attribute & HEX_BLINK )
            printf("       HEX_BLINK\n");
    }
    getch();
}
```

release_event( )

Format:

```
int release_event(event)
void *event;
```

Note The `void` data type is used because `release_event()` accepts pointers to structures of type `FRAME_EVENT`, `LEAD_EVENT`, `CH_EVENT` or `CHE_EVENT`.

Description:

Releases access to a specified event in the event buffer. The event's `held_count` parameter is decremented. If `held_count` is zero, the memory is said to be free, but it may not be resuable until all the events that are chronologically in front of the specified event have also been released by the processes that aquired access to them.

Return Values:

`SUCCESSFUL (0)`

`ERROR_1 (-1)`	The event was not found
`ERROR_2 (-2)`	A `NULL` event pointer was passed in.
`ERROR_3 (-3)`	The specified event pointer was not in the EBS buffer range.

See Also:

`get_event_bounds(), hold_event()`

Library Functions

release_event()

Example:

```
#include <dlib.include>
#include <retval.include>
#include <message.include>

main()
{
    MESSAGE message;
    int message_counter = 0;

    start_data();
    while(1)
    {
        if(read_message(&message, WAIT, WAIT_FOREVER))
            printf("Error reading queue.\n");
        else
        {
            message_counter += 1;
            printf("message #%d read.\n", message_counter);
            release_event(message.body.event.event_ptr);
        }
    }
}
```

resend_bops()

Format:

```
#include <retval.include>

int resend_bops(ptr, n, length)
char *ptr;
unsigned int n;
unsigned int length;
```

Description:

Retransmits the last bit-oriented protocol (HDLC, SDLC, X25, or X75) string sent using a sendf() call. If sendf() has not been called, the data held in the data link control hardware (possibly garbage) are sent out on the line. The resend_bops function allows modification of the sendf string. The sendf string may be sent many times (using resend_bops()) without redefining the string.

The ptr parameter points to a string of characters intended to replace the first n bytes of the sendf string. If ptr is NULL, or if n is zero, the sendf string is sent unchanged.

The length parameter defines the length of the new frame. If length is 0, the length remains the same as the original sendf string's length. If length is greater than the maximum allowable length (4106), length is set to 4106. If length is greater than the length of the original sendf string, the string is sent, with whatever data exist past the end of the buffer holding that string, concatenated on the end. The concatenation stops when the new string's length equals the value defined by length.

The resend_bops function overwrites the first n bytes of text in the original sendf string; it is not intended to insert text into that string.

resend_bops()

Note Since this function is intended to provide faster traffic generation, no check is made to be sure that a bit-oriented protocol (HDLC, SDLC, X25, or X75) has been selected. Selecting a character-oriented protocol (Char Asyn/Syn or BSC in the Setup Menu, COPS or BSC with set_protocol()) with this function is not supported.

Return Values:

SUCCESSFUL (0)

ERROR_5 (-5) There were problems communicating with the data link control hardware.

ERROR_10 (-10) The data link control hardware is not running.

See Also:

sendf()

resend_bops()

Example:

```
main()
{
   int i, result;
   char *ptr;

   ptr = "New";
   result = start_data();
   printf("result of start data is %d\n",result);
   result = sendf("Hi  there1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 ");
   printf("result of sendf is %d\n",result);
   for(i=0; i<30; i++)
      result = resend_bops(ptr,3,0);  /* replace first 3 chars */

   getch();
}
```

reset_pod()

Format:

```
int reset_pod()
```

Description:

Resets an attached pod by placing all leads in tri-state or not-driven states. Resets all pod hardware.

Return Values:

SUCCESSFUL (0)

ERROR_5 (-5) A fatal error occurred during an attempt to communicate with the protocol analyzer's data link control hardware.

See Also:

read_pod_id()

Example:

```
main()
{
   if (reset_pod())
      printf("Error resetting the 4954 pod.\n");
   else
      printf("The pod is reset.\n");

getch();
}
```

Library Functions

restore_cursor( )

Format:

```
void restore_cursor()
```

Description:

Restores the cursor to the screen position saved during the last call to `save_cursor()`.

Return Values:

None

See Also:

```
save_cursor(), set_cursor(), get_cursor()
```

Example:

```
main()
{
    int row = 2, col = 3;

    set_cursor(row, col);
    save_cursor();
    printf("Press a key: ");
    getch();
    restore_cursor();
    printf("Now press a key to exit: ");
    getch();
}
```

resync( )

Format:

```
#include <retval.include>

int resync()
```

Description:

Causes the protocol analyzer, when a character-oriented protocol is selected, to drop sync and begin looking for sync characters to re-establish sync. The data link control hardware must be running from a start_data() call before this function is called. The resync mode should be set to MANUAL with set_resync() before using this function

Note Due to speed considerations, no check is made for a valid character-oriented protocol (Char Asyn/Syn or BSC when set in the Setup Menu, COPS or BSC when set_protocol() is used) during this call, nor is a check made for resync mode equal to MANUAL.

Return Values:

SUCCESSFUL (0)

ERROR_5 (-5) There were problems communicating with the data link control hardware.

ERROR_10 (-10) The data link control hardware is not running.

See Also:

set_resync()

Example:

```
#include <retval.include>

main()
{
   int result;

   start_data();
   result = resync();
   if(result != SUCCESSFUL)
      printf("The resync failed with a value of %d\n", result);
   else
      printf("The resync was successful\n");

   getch();
}
```

roll_down()

Format:

```
void roll_down(start, end, num_lines)
int start, end, num_lines;
```

Description:

Rolls lines of text toward the bottom of the screen. The area affected by the scroll is bounded by the rows indicated by the start and end parameters. This text area is rolled down by the number of rows specified in num_lines.

Return Values:

None

See Also:

```
roll_up()
```

Example:

```
main()
{
    set_cursor(10,1);
    printf("hello world");
    while(1)
    {
        if((tolower(getch())) == 'd')
            roll_down(1,25,1);
        else
            roll_up(1,25,1);
    }
}
```

roll_up( )

Format:

```
void roll_up(start, end, num_lines)
int start, end, num_lines;
```

Description:

Rolls lines of text toward the top of the screen. The area affected by the scroll is bounded by the rows indicated by the `start` and `end` parameters. This text area is rolled up by the number of rows specified in `num_lines`.

Return Values:

None

See Also:

`roll_down()`

Example:

```
main()
{
    set_cursor(10,1);
    printf("hello world");
    while(1)
    {
        if((tolower(getch())) == 'd')
            roll_down(1,25,1);
        else
            roll_up(1,25,1);
    }
}
```

rs232_lock()

Format:

```
void rs232_lock()
```

Description:

Returns when the RS232 port has been locked by the calling process. If the port had been previously locked by another process, the calling process is blocked until it can lock the port.

Return Values:

None

See Also:

```
rs232_unlock()
```

Example:

```
main()
{
    char ch = 0;

    init_rs232();
    rs232_lock();
    while( ch != '*' )
        if(rs232_read_ready())
        {
            read_rs232(&ch);
            printf("The character read is '%c'.\n",ch);
        }
    rs232_unlock();
}
```

rs232_read_ready()

Format:

```
int rs232_read_ready()
```

Description:

Checks the status of the RS232 receive register. When the receive register is ready, the `read_rs232` function can be used to receive a character from the device connected to the port. If more than one process is using the port, the `rs232_lock` function should be called before any RS232 functions are called, and `rs232_unlock()` should be called after the process is finished with the port.

As with all the RS232 functions, this function must not be used until `init_rs232()` has been called.

Return Values:

Returns a 1 if a character is waiting in the receive register, or zero if there aren't any characters waiting in the register.

See Also:

```
rs232_write_ready(), rs232_lock(), rs232_unlock(), read_rs232()
```

rs232_read_ready()

Example:

```
main()
{
    char ch = 0;

    init_rs232();
    while( ch != '*' )
        if(rs232_read_ready())
        {
            read_rs232(&ch);
            printf("The character read is '%c'.\n",ch);
        }
}
```

Library Functions

rs232_unlock( )

Format:

```
void rs232_unlock()
```

Description:

Releases control of the RS232 port so that another process may lock and use the port. `rs232_unlock()` only works when called by the process that locked the port with `rs232_lock()`.

Return Values:

None

See Also:

```
rs232_lock()
```

Example:

```
main()
{
    char ch = 0;

    init_rs232();
    rs232_lock();
    while( ch != '*' )
        if(rs232_read_ready())
        {
            read_rs232(&ch);
            printf("The character read is '%c'.\n",ch);
        }
    rs232_unlock();
}
```

rs232_write_ready()

Format:

```
int rs232_write_ready()
```

Description:

Checks the status of the RS232 transmit register. When the transmit register is ready, the `write_rs232` function can be used to send a character to the device connected to the port. If more than one process is using the port, the `rs232_lock` function should be called before any RS232 functions are called, and `rs232_unlock()` should be called after the process is finished with the port.

As with all the RS232 functions, this function must not be used until `init_rs232()` has been called.

Return Values:

Returns a 1 if the transmit register is empty, and returns zero otherwise.

See Also:

```
rs232_read_ready(), write_rs232(), rs232_lock(), rs232_unlock()
```

Example:

```
#include <conio.include>

/* A dumb terminal emulator, terminates after the '~' character is typed */
/* on the keyboard....                                                   */

main()
{
   char ch = 0;

   init_rs232();
   printf("Writing to the RS232 port - press RESET to exit\n\n");
   while( ch != '~' )
   {
      if(is_key_avail())
      {
         ch = getch();
         while (!rs232_write_ready()) ;
         write_rs232(ch);
      }
      if(rs232_read_ready())
      {
         read_rs232(&ch);
         putch(ch);
         ch = 0;
      }
   }
}
```

save_cursor()

Format:

```
void save_cursor()
```

Description:

Saves the current cursor position so that the row and column values can be restored by `restore_cursor()`.

Return Values:

None

See Also:

```
restore_cursor()
```

Example:

```
main()
{
    int row = 2, col = 3;

    set_cursor(row, col);
    save_cursor();
    printf("Press a key: ");
    getch();
    restore_cursor();
    printf("Now press a key to exit: ");
    getch();
}
```

scanf( )

Format:

```
int scanf(format, args)
char *format;
char *args;
```

Description:

Takes text characters from the standard input stream (stdin), checks the character types against conversion characters imbedded in a control string pointed to by the format parameter, and places matching text in the fields pointed to by the args list.

The following scanf() example shows the main components of the function:

```
scanf("%f%s", &fltptr, &strptr);
```

The string "%f%s" is a control string (format) with two control items (both conversion characters), one indicating a floating point value (%f), and the other (%s) indicating a string. The other arguments, &fltptr and &strptr, define the argument list (args). If scanf() finds floating point characters, it places them in the memory location pointed to by fltptr; if a character string is found next, it is placed in the memory location pointed to by strptr.

A control string contains these control items:

- Conversion specifications
- Optional white space characters (tab, space, newline)
- Optional alphanumeric characters (not white space, and not part of a conversion specification).

The scanf function works its way through a control string from left to right, trying to match each control item to a portion of the input stream. During the matching process, scanf() fetches characters one at a time from the input stream. If a character is found which doesn't match the type specifier for the corresponding conversion specificiation, scanf() pushes the character back onto the input stream and finishes processing the current control item. This "pushing back" frequently gives unexpected results when a stream is used later by other I/O functions, such as getc(), as well as by scanf() itself, if it is used again.

scanf( )

A conversion specification has the form:

```
%[*][width][l]type
```

Each field enclosed in braces "[ ]" is optional and consists of a single character or number signifying a particular format option. The simplest possible conversion specification contains a percent sign (%) and a type, or conversion character (ex: %f)

The optional fields are defined below, and conversion characters are discussed later in this segment.

*

Assignment suppression character. The current stream is scanned, but not saved. The function goes on to the next control string item.

width

This field specifies the maximum number of characters to be fetched for the conversion.

l

This field indicates that the argument is a pointer to a long data type - the exact type (for example, long decimal, long hex, long unsigned) is determined by the conversion character.

The conversion character format is as follows:

character	type of argument	expected input format
d	pointer to int	signed decimal
u	pointer to int	unsigned decimal
x	pointer to int	unsigned hexadecimal
o	pointer to int	unsigned octal
e,f	pointer to float	floating point
c	pointer to char	single character
s	pointer to char array	character string

When a conversion specification is encountered in the control string, the scanf function skips leading white space on the input stream, then collects characters from the stream until it encounters one that is not appropriate for the corresponding conversion character. That character is pushed back onto the input string.

As long as the conversion specification didn't request assignment suppression (see '*', above), the text string that was read from the keyboard is converted to the format specified by the conversion specification, the result is placed in the location pointed to by the corresponding args argument, the next argument becomes current, and the function proceeds to the next control string item.

If assignment suppression was requested, the `scanf` function ignores the input characters and goes on the the next control item.

If an ordinary character is found in the control string, outside any conversion specfication, `scanf()` fetches the next character. If that character matches the character in the control string, the function goes on to the next control string item, ignoring the input character. If there is no match, `scanf()` terminates.

If a white space character is found in the control string, the `scanf` function fetches input characters until the first non-white space character is read. The non-white space character is pushed back onto the input stream and `scanf()` proceeds to the next item in the control string.

Return Values:

Returns the number of items converted and assigned to memory locations in `args`. Unmatched items, since they are not assigned to `args`, are not included in the count.

See Also:

`fscanf(), sscanf()`

Library Functions

scanf()

Example:

```
#include <stdio.include>

main()
{
   char instr[70];

   scanf("%s",instr);
   printf("The string read from the input is %s.", instr);
   getch();
}
```

send_message()

Format:

```
#include <message.include>
#include <retval.include>

int send_message(QID, message, options);
long QID;
MESSAGE *message;
int options;
```

Description:

Sends a message to the queue identified by the `QID` (queue identifier) parameter. The `options` parameter indicates whether or not additional action is necessary when the message is sent. Constant values for the `options` parameter are defined in the `message.include` file and are outlined below:

options	Description
ZERO	No addition action is taken. The message is processed normally.
EXPEDITE	The message is placed at the beginning of the destination process's message queue.

`send_message()` provides communication between processes running in the DataCommC environment. The function expects that the process associated with the specified queue is running, and that the `QID` for that process queue has not been changed.

Return Values:

SUCCESSFUL (0)	The message was sent.
QUEUE_DELETED (-1)	The queue has been deleted

send_message( )

INVALID_QUEUE_NUMBER (-2)	An invalid queue number was given.
NO_QUEUE_BUFFERS (-5)	There weren't any system buffers available.
MAX_MSGS_EXCEEDED (-6)	The queue was full.

See Also:

read_message(), is_msg_avail()

Example:

```
#include <system.include>
#include <message.include>
#include <retval.include>
/* Sends an exit message to the process that spawned it.  send_message() returns an */
/* error if the parent is no longer running, the _parent_QID variable was modified, */
/* or if the process calling the exit_process() routine has been started by the */
/* run-time  routine. */

main()
{
   printf("Press a key to send parent the exit message and exit this process:\n");
   getch();
   exit_process(1);
}

/* Make the message type unique so the parent process doesn't mistake it for another */
#define EXIT_USER_PROCESS  25

exit_process(exit_code)
int exit_code;
{
   MESSAGE msg;

   msg.type = EXIT_USER_PROCESS;
   msg.body.user_message.user_long   = _process_QID;
   msg.body.user_message.user_int1 = exit_code;
   if(send_message(_parent_QID,&msg,0))
      {
      printf("Error sending exit message to parent. Press a key to exit: ");
      getch();
      }
   exit();
}
```

Library Functions

sendf( )

Format:

```
#include <retval.include>
#include <dlib.include>

int sendf(format, args);
char *format;
char *args;
```

Description:

Sends a formatted string to the line (by way of the protocol analyzer's level 1 control hardware). The formatting is controlled by the arguments referred to above, and is similar to the formatting shown in the `printf()` and `scanf()` functions. The `format` parameter represents a control string containing format conversion characters, and `args` represents an argument list. The control string is always null-terminated. For example:

```
sendf("%f%2n%s", BAD_FCS, 0x00, 0x04, "L2 data field");
```

In this example, `"%f%2n%s"` is a control string that sends a frame check sequence (`BAD_FCS`),two 8-bit hex values (`0x00` and `0x04`), and a character string (`"L2 data field"`).

The control string is read left to right. As each control string element is read, the character specification it contains is used to modify the corresponding field(s) in the argument list. Any character read that is not part of a character specification is translated to the current datacode and parity before being sent (for example, `"hello world"` in the control string: `"%nhello world%s"`).

A character specification has the form:

```
%[dimension]conversion character
```

The dimension field is optional and may refer to either the number of argument list fields , the value of an argument, or the length of a field to be sent, depending on which conversion character it is modifying. The dimension field consists of either a constant or an asterisk (*) preceding the conversion character. If an asterisk precedes the conversion character, the next

Library Functions

field in the argument list is interpreted as the integer length or number of arguments to be sent. For example, the sendf() statement below is the same as the one shown on the previous page, except that the number of 8-bit values to be sent is now included in the argument list.

```
sendf("%f%*n%s", BAD_FCS, 2, 0x00, 0x04, "L2 data field");
```

The conversion character format is as follows:

character	type of argument	output format
n	integer	8-bit value
b	pointer to buffer	hex data dump
c	frame_type	variable (?)
s	string	character string
f	FCS type	hex value

n This conversion character allows 8-bit values to be sent to the protocol analyzer's data link control hardware. The dimension field determines how many 8-bit values appear in the final send sequence. The ascii.include and ebcdic.include files contain constant values and definitions for characters in the standard ASCII and EBCDIC character sets.

b This conversion character provides a pointer to a buffer of hex data. The dimension field specifies the length of the buffer. The buffer pointer must be included in the appropriate place in the argument list. For example:

```
char *buff_ptr;         /* set up buffer pointer */
.
.
sendf("%32b", buff_ptr);
```

sendf( )

c The HP 18356A ISDN Solution uses this conversion character to select either the primary or secondary channel for data transmission through `sendf()`. If the dimension field is 1, the primary channel is selected, if it is 2, the secondary channel is selected. This conversion character must be used in combination with another conversion character that formats or specifies the data to be sent.

s This conversion character creates an ASCII (null-terminated) string. The data will be translated to the current datacode and parity (see `set_protocol()` function). The dimension field can be used to set an absolute length for the string, so that null characters can be included in the string. If the dimension field is not used, the string length is calculated to be the number of characters found before a null character is detected.

f This conversion character adds the specified FCS (frame check sequence) to the send string whenever `"%f"` is found in the control string, and a corresponding FCS parameter in an argument list field. If there is no `"%f"` element in the control string, `GOOD_FCS` is sent. The constant values are:

GOOD_FCS	Good FCS
BAD_FCS	Bad FCS
ABORT_FCS	ABORT/BREAK sequence
NO_FCS	No FCS sent (only for BSC protocol)

These constant values are defined in the `dlib.include` file.

Note The send string must always contain at least 2 bytes of data.

Return Values:

SUCCESSFUL (0)

Library Functions

ERROR_1	(-1)	An error was found in the formatting.
ERROR_2	(-2)	The data link control hardware could not send this string.
ERROR_3	(-3)	Invalid FCS type specified.
ERROR_4	(-4)	Illegal frame type encountered.
ERROR_5	(-5)	An error occurred during an attempt to communicate with the data link control hardware.
ERROR_6	(-6)	The dlc hardware is not configured to transmit.
ERROR_7	(-7)	A BOPS send string was greater than 4106 bytes or less than 2 bytes, or a COPS send string was greater than 4106 bytes or less than 1 byte.
ERROR_10	(-10)	The dlc hardware is not running.

See Also:

start_data()

Example:

```
#include <dlib.include>
#include <message.include>
#include <retval.include>

main()
{
    char buffer[10];
    int i;
    MESSAGE msg;

    init_datacomm();
```

```
    for (i = 0; i < 500; i++)
    {
        sprintf(buffer,"%d", i);
        set_cursor(10, 10);
        printf("buffer = %s, length = %d", buffer, strlen(buffer));
        sendf("%s(%n)",buffer,strlen(buffer));
        while(is_msg_avail() )
            read_message(&msg, WAIT, WAIT_FOREVER);
        release_event(msg.body.event.event_ptr);
    }
    stop_data();
}

/* Initalize the 4954 as a DTE */

init_datacomm()
{
    int result, ch;

    result = set_channelconfig(DTE, TX);
    if(result != 0)
        printf("config(DTE, TX) error - result = %d\n", result);
    result = set_channelconfig(DCE, RX);
    if(result != 0)
        printf("config(DCE, RX) error - result = %d\n", result);
    set_buffer_sizes(50, 50);
    result = start_data();
    if(result != 0)
        printf("start_data() error - result = %d\n", result);
}
```

set_attribute( )

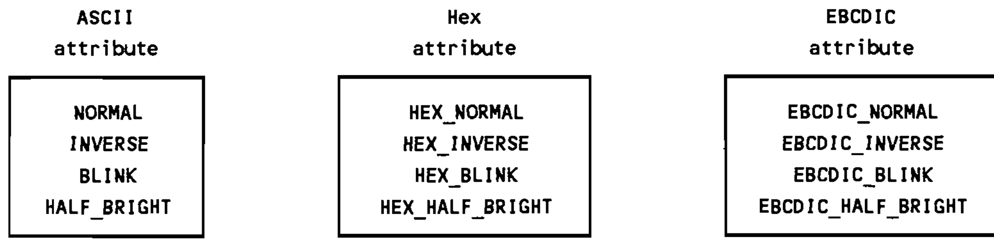
Format:

```
#include <video.include>

void set_attribute(attribute)
int attribute;
```

Description:

Sets the value of the current display attribute. The constant values defined in the `video.include` file generate normal, inverse-video or low-intensity text, as well as text that blinks for either the ASCII, Hex or EBCDIC character set.



These attribute values may be set individually or combined using an arithmetic OR statement. The example program selects low-intensity, inverse-video characters.

set_attribute( )

Setting the attribute to SPECIAL enables the display of graphics characters from the currently selected display bank. For complete listings of the graphics character sets in the protocol analyzer's four display banks, refer to appendix A of this manual, "Video Character Sets."

Once the display attribute is defined, it retains its new value until set_attribute() is called again. Any text entered with putc(), putch(), puts(), center() or printf() is generated using the current attribute.

Return Values:

None

See Also:

get_attribute(), set_disp_bank()

Example:

```
#include <video.include>

main()
{
   int attribute;

   set_attribute(INVERSE | HALF_BRIGHT);
   attribute = get_attribute();
   printf("The following screen attributes are set:\n\n");
   if((attribute & NORMAL) == NORMAL)
      printf("       NORMAL\n");
   if((attribute & SPECIAL) == SPECIAL)
      printf("       SPECIAL\n");
   if((attribute & INVERSE) == INVERSE)
      printf("       INVERSE\n");
   if((attribute & HALF_BRIGHT) == HALF_BRIGHT)
      printf("       HALF_BRIGHT\n");
   if((attribute & BLINK) == BLINK)
      printf("       BLINK\n");
   if((attribute  &  NORMAL) == 0)
   {
      if(attribute & HEX_NORMAL)
         printf("       HEX_NORMAL\n");
      if(attribute & HEX_INVERSE )
         printf("       HEX_INVERSE\n");
      if(attribute & HEX_BLINK )
         printf("       HEX_BLINK\n");
   }
   getch();
}
```

set_bcc()

Format:

```
#include <dlib.include>
#include <retval.include>

int set_bcc(startbcc1, startbcc2, stopbcc1, stopbcc2)
char startbcc1, startbcc2, stopbcc1, stopbcc2;
```

Description:

Sets the protocol rules for calculating the block check character (bcc) as long as the protocol has been set to COPS and the errorcheck is any available value except NO_ERROR_CHECK (see set_protocol()).

The startbcc1 and startbcc2 parameters are used to start bcc accumulation. Accumulation begins when either of these two values are received. Similarly, when either the stopbcc1 or stopbcc2 parameter values are received, bcc accumulation ends.

Since set_bcc() affects the protocol analyzer's data link control setup, it must be called only when the dlc hardware is not active, that is, either before start_data() is called, or after stop_data() is called.

Return Values:

SUCCESSFUL (0)

ERROR_1 (-1) The protocol was not COPS.

ERROR_2 (-2) The errorcheck was NO_ERROR_CHECK.

ERROR_10 (-10) The data link control hardware has already been started. The dlc hardware must be stopped with stop_data() before any changes to the dlc configuration can be made.

See Also:

get_startbcc(), get_stopbcc(), set_protocol()

Example:

```
#include <ascii.include>       /* for as_STX, as_SOH, as_ETX and as_EOT */
#include <retval.include>      /* for SUCCESSFUL */

main()
{
   int startbcc1 = as_STX,
          startbcc2 = as_SOH,
          stopbcc1  = as_ETX,
          stopbcc2  = as_EOT;
   int result;

   if((result = set_bcc(startbcc1, startbcc2, stopbcc1, stopbcc2)) != SUCCESSFUL)
   {
      printf("Error #%d returned from set_bcc().\n",result);
      getch();
      exit();
   }

   printf("Start and stop characters for the BCC are set.");
   getch();
}
```

Library Functions

set_bitrate( )

Format:

```
#include <dlib.include>
#include <retval.include>

int set_bitrate(bitrate)
long bitrate;
```

Description:

Sets the bitrate for the clock provided on the HP 4954 Protocol Analyzer. This function also affects the resolution of the timestamp on the data. If the value selected is less than the minimum value (10 bps), the bitrate defaults to the minimum value. Similarly, if the bitrate valued selected is larger than the maximum value (256k bps), the bitrate defaults to the maximum value. Nominal performance is not guaranteed when the bitrate is greater than or equal to 100k bps. `set_bitrate()` affects the protocol analyzer's data link control setup; any changes must be made either before the dlc hardware is started with `start_data()`, or after `stop_data()` has halted the dlc.

Return Values:

`SUCCESSFUL (0)`

`WARNING_1 (1)` The value of the `bitrate` parameter exceeded the maximum allowable value (256k bps); the maximum value is substituted.

`WARNING_2 (2)` The value of the bitrate parameter is less than the minimum allowable value (10 bps); the minimum value is substituted.

`ERROR_10 (-10)` The data link control hardware has already been started. The dlc hardware must be stopped with `stop_data()` before any changes to the dlc configuration can be made.

See Also:

get_bitrate()

Example:

```
main()
{
    long bitrate;

    set_bitrate(1200L);
    bitrate = 0;
    get_bitrate(&bitrate);
    printf("The bitrate is %ld.",bitrate);
    getch();
}
```

set_buffer_sizes()

Format:

```
#include <dlib.include>
#include <retval.include>

int set_buffer_sizes(DTE_size, DCE_size)
int DTE_size, DCE_size;
```

Description:

Sets the sizes for the primary DTE and DCE data buffers and sets the secondary buffers (SDTE and SDCE) sizes to zero. The primary buffer sizes (`DTE_size` and `DCE_size`) must be defined as percentages of the total buffer space. The total buffer space is 205676 bytes.

If `start_data()` has already been called, and the data link control hardware is running when `set_buffer_sizes()` is called, both the DTE and DCE buffer sizes are set to 50 percent of the total buffer (102838 bytes each).

Return Values:

`SUCCESSFUL (0)`

`ERROR_1 (-1)` One or both of the percentages were less than zero.

`ERROR_2 (-2)` One or both of the percentages were greater than one hundred.

`ERROR_3 (-3)` The combined percentages were greater than one hundred.

See Also:

`start_data()`

Example:

```
#include <retval.include>

main()
{
    int result;

    if((result = set_buffer_sizes(75, 25)) != SUCCESSFUL)
    {
        printf("Error #%d returned from set_buffer_sizes().\n", result);
        getch();
        exit();
    }
    printf("Buffer sizes set.");
    getch();
}
```

set_channelconfig( )

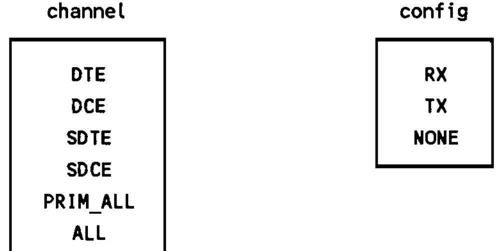
Format:

```
#include <dlib.include>
#include <retval.include>

int set_channelconfig(channel, config)
char channel, config;
```

Description:

Sets the configuration of the specified channel. Any of the protocol analyzers' channels may be set to receive data or to idle, but only one may be selected to transmit. Constant values for the channel and config parameters are defined in the dlib.include file and are shown below:



The channels include the primary DTE and DCE (DTE and DCE) and the secondary DTE and DCE (SDTE and SDCE). The secondary channels are intended for use with the HP 18356A ISDN Solution. All four channels may be set to receive data if channel=ALL and config=RX; both primary channels may be selected to receive if channel=PRIM_ALL and config=RX.

If channel is set to PRIM_ALL or ALL, the config parameter must be RX.

Note Only one channel can be configured as a transmitter at a time. If you call set_channelconfig() requesting transmit capability when a different channel has already been set up to transmit, the function terminates in error.

The channel/config setup determines whether the protocol analyzer acts in monitor or simulate mode, and whether the Event Buffer Service (EBS) is active. Whenever any channel is selected to receive data, the Event Buffer begins collecting data (after start_data() is called). If a channel is selected to transmit, simulate mode is enabled. If the transmitter is not enabled, the protocol analyzer is configured for monitor mode.

The table below shows the possible combinations for the primary channels (combinations for the secondary channels are similar). In the table, the state of the protocol analyzer is represented by the boxed text at the intersection of the DTE and DCE channel configurations. For example, when DTE==RX and DCE==TX, the protocol analyzer is in simulate mode because a transmitter is enabled, and the Event Buffer is ready to collect data because a receiver is enabled.

		DTE		
		RX	TX	NONE
DCE	RX	monitor EBS	simulate EBS	monitor EBS
	TX	simulate EBS	ERROR_1	simulate
	NONE	monitor EBS	simulate	monitor

Return Values:

SUCCESSFUL (0)

Library Functions

set_channelconfig( )

`WARNING_1 (1)` The value of one or more of the parameter values is unknown. All four channels are set to `RX`.

`ERROR_1 (-1)` Transmit (`TX`) was selected while transmit capability had already been selected for another channel.

`ERROR_2 (-2)` The `channel` parameter was set to `ALL` or `PRIM_ALL` but `config` was not set to `RX`.

`ERROR_10 (-10)` The data link control hardware has already been started. The dlc hardware must be stopped with `stop_data()` before any changes to the dlc configuration can be made.

See Also:

`get_channelconfig()`

Library Functions

Example:

```
#include <dlib.include>
#include <retval.include>

main()
{
   int result;

   if((result = set_channelconfig(DTE, RX)) != SUCCESSFUL)
   {
      printf("Error #%d returned from set_channelconfig().\n", result);
      getch();
      exit();
   }
   printf("DTE channel configured to receive.");
   getch();
}
```

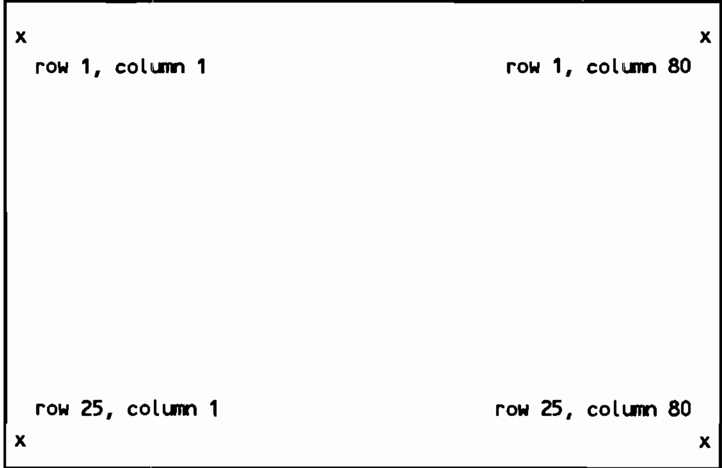
set_cursor()

Format:

```
void set_cursor(row, column)
int row, column;
```

Description:

Places the cursor on the row and column indicated. The screen boundaries are shown below:



Return Values:

None

See Also:

```
get_cursor()
```

set_cursor( )

Example:

```
main()
{
   set_cursor(15, 35);
   printf("This string starts at screen coordinates (15, 35).");
   getch();
}
```

set_data_source( )

Format:

```
#include <dlib.include>
#include <retval.include>

int set_data_source(data_source, data_file)
char data_source;
char *data_file;
```

Description:

Allows a program to set either the line or a disc file as the source for the data buffer input. The `set_data_source` function must be called before the data link control hardware is started when the program is going to run from a disc file.

`DISC_RUN` allows data to be brought in from the file indicated by the `data_file` parameter. Files resident on any of the protocol analyzers' internal or attached disc drives may be brought in by specifying the device name in the `data_file` parameter. See the *DataCommC Programming Language User's Guide* for a list of possible disc drive device names. Hard discs may also include subdirectory names in the path. For example, "`c:C/User/Mydata.bufferdata`" could be a valid path/file name for the protocol analyzer's internal hard disc if the file "`Mydata.bufferdata`" exists under the "`C/User`" subdirectory. The file indicated by `data_file` must exist and have a `bufferdata`, `menus&data` or `ext.rundata` extension.

The `data_file` parameter is ignored if `data_source==LINE_RUN`. When `data_source==DISC_RUN`, the file is opened automatically, and is closed when `stop_data()` is called. Also when `data_source==DISC_RUN`, the protocol analyzer is automatically configured for monitoring; it is not possible to send data or set leads.

If the source of data has been set to `DISC_RUN`, `set_data_source()` must be called before each `start_data()` call.

Return Values:

`SUCCESSFUL (0)` The operation was successful.

set_data_source()

`WARNING_1 (1)` The value of one or more of the parameter values is unknown. It is assumed to be the default. The default for the `data_file` parameter is `NULL`.

`ERROR_1 (-1)` The file specified by `data_file` does not exist, or the file extension is something other than `bufferdata`, `menus&data` or `ext.rundata`.

See Also:

get_data_source(), start_data(), stop_data()

Example:

```
#include <dlib.include>
#include <retval.include>

main()
{
   int result;
   char *runfile;

   runfile = "c:run010189.menus&data";
   if((result = set_data_source(DISC_RUN, runfile)) != SUCCESSFUL)
   {
      printf("Error #%d returned from set_data_source().\n", result);
      getch();
      exit();
   }
   printf("The 4954 is configured to run from disk file '%s'.", runfile);
   getch();
}
```

set_disp_bank( )

Format:

```
#include <video.include>

void set_disp_bank(disp_bank)
int disp_bank;
```

Description:

Selects one of four special display banks resident in the protocol analyzer. The display banks contain graphics character sets that may be used to create bar charts for data, boxes to offset windowed text, or japanese characters. Tables containing the display bank characters are included in appendix A, "Video Character Sets," in this manual. Constant values for the disp_bank parameter are defined in the video.include file, and are shown below:

disp_bank	value
DISP_BANK0	0x000
DISP_BANK1	0x100
DISP_BANK2	0x200
DISP_BANK3	0x300

The set_display_bank function has no effect unless the display attribute has been set to SPECIAL. This can be accomplished by calling:

```
set_attribute(SPECIAL);
```

before calling set_disp_bank(). See set_attribute() for more information.

The display banks can also been seen by pressing `Ext Test/ Set Clock` from the protocol analyzer's Top Level Menu, then selecting `Display Patterns`. Any of the four banks may be viewed by pressing the appropriate softkey.

set_disp_bank()

Return Values:

None

See Also:

get_attribute(), set_attribute()

Example:

```
#include <video.include>

main()
{
    int x, z;

    set_attribute(SPECIAL);
    set_disp_bank(DISP_BANK0);
    for(x = 128; x < 256; x++)
    {
        putch(x);
        printf("  ");
        z = (x - 7) % 24;
        if(!z)
            printf("\n\n");
    }
    getch();
}
```

set_duplex( )

Format:

```
#include <dlib.include>

int set_duplex(duplex)
int duplex;
```

Description:

Modifies the duplex value for the conversation between DTE and DCE devices by passing a constant value through duplex parameter. The constant value may be either:

duplex	value
HDX	1
FDX	2

These values are located in the dlib.include file.

Return Values:

SUCCESSFUL (0)

ERROR_1 (-1) An invalid parameter was passed to the function.

ERROR_10 (-10) The data link control hardware has already been started. The dlc hardware must be stopped with stop_data() before any changes to the dlc configuration can be made.

See Also:

get_duplex()

Library Functions

set_duplex()

Example:

```
#include <dlib.include>
#include <retval.include>
main()
{
    int result;

    result = set_duplex(FDX);
    if (result != SUCCESSFUL)
    {
        printf("set_duplex() failed with a value of %d\n",result);
    }
    else
    {
        printf("There was a problem setting the duplex\n");
    }
    getch();
}
```

set_error_handler( )

Format:

```
void set_error_handler(error_QID)
long error_QID;
```

Description:

Designates `error_QID` as the queue to handle non-fatal errors. If `error_QID` equals zero, the default system error handler is used.

Return Values:

None

See Also:

```
error_notification()
```

Library Functions

set_error_handler()

Example:

```
#include <message.include>
#include <system.include>

#define The_sun_sets_in_the_west 1
main()
{
    MESSAGE message;
    int error_count = 0;

    set_error_handler(_process_QID); /* tell the run-time system that this */
                                     /* process will handle all non-fatal  */
                                     /* errors                             */
    while( The_sun_sets_in_the_west )
    {
        read_message(&message,WAIT,WAIT_FOREVER);
        if(message.type == ERROR)
            if(++error_count == 10) /* exit run-time environment if more than */
                                    /* 10 non-fatal errors are detected       */
                error_notification("Error limit exceeded, exiting to shell..",FATAL_ERROR);
    }
}
```

set_ignored_leads( )

Format:

```
int set_ignored_leads(lead_id_map)
unsigned long lead_id_map;
```

Description:

Programs the protocol analyzer's data link control hardware to ignore transitions on leads that are bit-mapped in lead_id_map with a 1. Lead 0 (0x0001) corresponds to bit 0 of lead_id_map, lead 1 (0x0002) corresponds to bit 1, and so on. Only leads 0 through 14 (0x4000) can be chosen to be ignored. See the leads.include file for definitions of the lead constants. The leads and their constant values are also shown below. If lead_id_map = 0x0000, none of the leads are ignored.

set_ignored_leads()

Return Values:

SUCCESSFUL (0)

ERROR_10 (-10) The data link control hardware was already running, and the leads could not be configured. Use stop_data() to halt the dlc hardware before set_ignored_leads() is called.

See Also:

get_ignored_leads()

Example:

```
#include <leads.include>
#include <retval.include>

main()
{
    long leads = DTE_LEAD | RTS;
    int result;

    if((result = set_ignored_leads(leads)) != SUCCESSFUL)
    {
        printf("Error #%d returned from set_ignored_leads().\n",result);
        getch();
        exit();
    }
    printf("The leads to ignore have been set.");
    getch();
}
```

set_lead( )

Format:

```
#include <leads.include>
#include <dlib.include>
#include <retval.include>

int set_lead(lead_id, lead_state)
unsigned long lead_id;
unsigned int lead_state;
```

Description:

Sets the lead specified by lead_id to the state (ON, OFF or NOT_DRIVEN) defined in lead_state. The lead_id parameter refers to leads defined by RS232C, MIL188C, RS449 or V.35 interface standards. Valid lead_id definitions are located in the leads.include file and are shown below:

RS232C/MIL188C

set_lead()

Return Values:

SUCCESSFUL (0)	
ERROR_1 (-1)	The lead_id definition is invalid.
ERROR_2 (-2)	The lead_state definition is invalid.
ERROR_3 (-3)	The protocol analyzer is in monitor mode and leads cannot be set (see set_channelconfig()).
ERROR_5 (-5)	Problems occurred while attempting to communicate with the protocol analyzer's data link control hardware.

See Also:

get_lead(), set_ignored_leads(), get_ignored_leads()

Example:

```
#include <dlib.include>
#include <leads.include>
#include <retval.include>

main()
{
   int result;

   if((result = start_data()) != SUCCESSFUL)
   {
      printf("Error #%d returned from start_data().\n",result);
      getch();
      exit();
   }
   if((result = set_lead(RTS,ON)) != SUCCESSFUL)
   {
      printf("Error #%d returned from set_lead().\n",result);
      getch();
      exit();
   }
   printf("The RTS lead is now on.");
   getch();
}
```

set_lead_control()

Format:

```
#include <dlib.include>
#include <retval.include>
    :
int set_lead_control(lead_control)
int lead_control;
```

Description:

Modifies the lead_control value for the conversation between the DTE and DCE devices by passing a constant value through the `lead_control` parameter. The constant value is either:

lead_control	value
LEAD_CONTROL_DEFAULT	2
LEAD_CONTROL_USER_DEF	1

These `lead_control` values are located in the `dlib.include` file.

Return Values:

SUCCESSFUL (0)

ERROR_1 (-1) An invalid parameter was passed to the function.

ERROR_10 (-10) The data link control hardware has already been started. The dlc hardware must be stopped with `stop_data()` before any changes to the dlc configuration can be made.

See also:

`start_data(), get_lead_control()`

Example:

```
#include <dlib.include>
#include <retval.include>

main()
{
    int result;
    result = set_lead_control(LEAD_CONTROL_DEFAULT);
    if (result != SUCCESSFUL)
    {
        printf("set_lead_control() failed with a value of %d\n",result);
    }
    else
    {
        printf("There was a problem setting the lead control\n");
    }
    getch();
}
```

set_protocol( )

Format:

```
#include <dlib.include>
#include <retval.include>

int set_protocol(protocol, mode, datacode, parity, errorcheck)
int protocol, mode, datacode, parity, errorcheck;
```

Description:

Modifies certain datacomm parameters (protocol, mode, datacode, parity, and errorcheck) that are otherwise only accessible through the protocol analyzer's Setup menu. The DataCommC Programming Language supports bit-oriented and synchronous and asynchronous character-oriented protocols. Choices for the protocol parameter include any of the following:

protocol	
HDLC	High-level Data Link Control
SDLC	Synchronous Data Link Control
X25	X.25 - Level 3 Bit-oriented Protocol
X75	X.75 - Level 3 Bit-oriented Protocol
COPS	Character-Oriented Protocols
BSC	Bisync
NO_CHANGE	Not a protocol - allows old choice to remain unchanged

The choices for mode, datacode, parity, and errorcheck depend on the protocol chosen, and lists of the choices available for each protocol are shown on the following pages. If start_data() is called, the values selected for the set_protocol() parameters are downloaded to the protocol

analyzer's data link control hardware, which uses them to interpret received data and to translate outgoing data into the proper format.

If a protocol is chosen that does not match the choices shown for the `protocol` parameter, the following defaults are passed to the dlc hardware (`parity` is not set):

protocol	mode	datacode	parity	errorcheck
HDLC	SYNC_DCE	EBCDIC	-----------	CRC_CCITT

Note

`set_protocol()` affects and is affected by the protocol analyzer's Setup Menu. It can change the system variables associated with its own parameters, the same variables that the Setup Menu uses. Any parameters successfully altered by the function appear in the Setup Menu even after program execution has terminated.

Similarly, if the `NO_CHANGE` choice is selected for any `set_protocol()` parameter, the function fetches the associated system variable, which may have been previously selected in the Setup Menu, and passes it to the dlc hardware.

Since the system variables are used in this way, `set_protocol()` does not have to be called in a program as long as its parameters have already been selected with the Setup Menu.

There are differences between `set_protocol()` and the Setup Menu. If the Mode and Sync softkeys are pressed in the Setup Menu, there is a choice of whether the clock source for the DTE channel is supplied from the DCE or the DTE device. In the `set_protocol` function, the same choice exists, but the mode and clock source are selected at the same time using the `mode` parameter. `SYNC_DCE` sets the `mode` to synchronous and selects the DCE device as the source for the DTE channel clock, while `SYNC_DTE` sets the mode to synchronous and selects the DTE device as the source for the DTE channel clock.

set_protocol( )

The datacode parameter affects how data is sent when the sendf() function is used. The ASCII string specified in the sendf() call is translated to the datacode specified by set_protocol(). The parity parameter affects sendf() in the same manner. While the datacode parameter does not affect the dlc, parity affects it when the COPS or BSC protocol is selected.

The value selected for errorcheck determines the error check used on all frames unless sendf() is called with BAD_FCS, ABORT_FCS or NO_FCS selected as the FCS parameter (see sendf(), conversion character %f).

Note If an unknown value is passed to one of the parameters, the default value for that parameter under the current protocol is used, and set_protocol() returns a warning (WARNING_1). If, however, the value passed is valid for the parameter, but incompatible with the current protocol and/or other parameters, the function returns in error (ERROR_1), and none of the requested changes are made.

Each protocol (starting with HDLC on the next page) is shown with its normal defaults ranged from left to right across the top row of choices. If a protocol is selected without defining the other parameters (NO_CHANGE is passed in instead), whatever values had previously been assigned to those parameters are used again.

For example, if the following function was called in a DataCommC program:

```
set_protocol(X25, SYNC_DCE, ASCII7, ODD_PARITY, CRC_CCITT);
```

the function would return successfully, and the protocol analyzer's Setup menu would reflect set_protocol()'s parameter values. Calling the function again with these values:

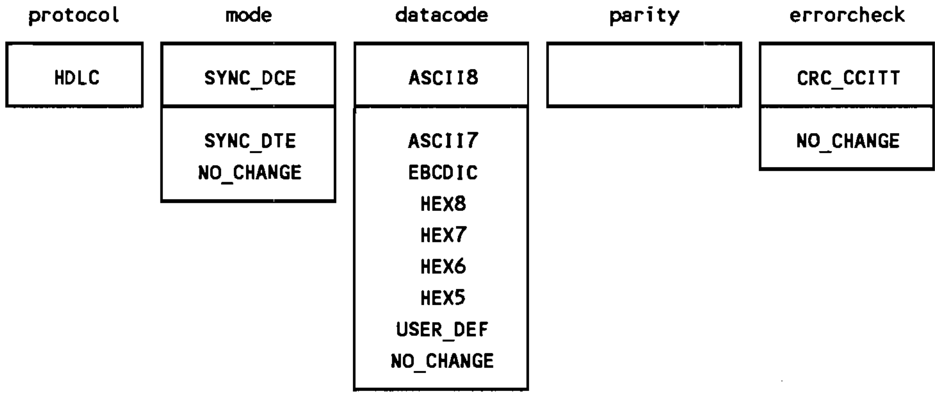
```
set_protocol(COPS, ASYNC_1, NO_CHANGE, NO_CHANGE, NO_CHANGE);
```

is equivalent to:

```
set_protocol(COPS, ASYNC_1, ASCII7, ODD_PARITY, CRC_CCITT);
```

which would return WARNING_1 since CRC_CCITT is not recognized by COPS. The default COPS errorcheck value, NO_ERROR_CHECK, would be substituted when the values were downloaded to the dlc.

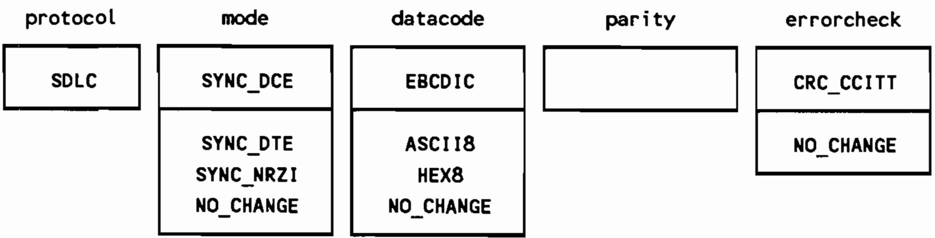
HDLC, SDLC, X25 and X75 are all bit-oriented protocols (BOPS). Bit-oriented protocols use flag characters (0x7E) to idle the line; therefore the mode parameter choices include only the synchronous modes: SYNC_DCE and SYNC_DTE. SDLC also includes SYNC_NRZI as a mode choice.



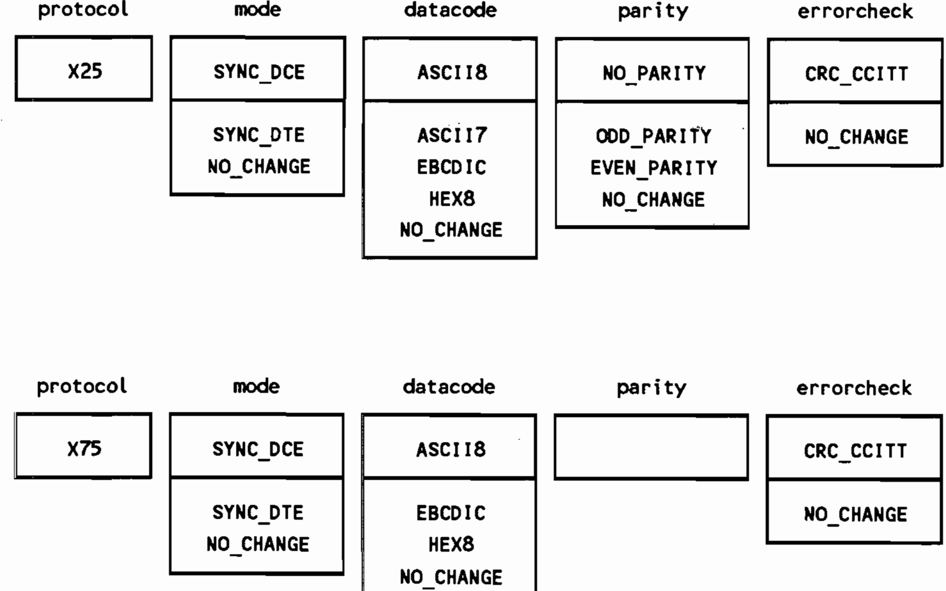
HDLC, BSC and COPS protocols allow the choice of user-defined data codes; however, the data code cannot be defined in the DataCommC environment. The only way to define a data code is through the protocol analyzer's Setup Menu; the operation is described in appendix E of *The HP 4954A Operating Manual*. If USER_DEF is used as a datacode choice, whatever user-defined data code is specified in the Setup Menu is downloaded to the dlc. The Setup Menu has a default user-defined data code in which every character code is a "Don't Care" character; this data code is used when a data code has not been loaded or defined.

Although set_protocol() completely ignores whatever value is passed to parity for HDLC, a value must be passed in anyway.

set_protocol()



Although set_protocol() completely ignores whatever value is passed in for parity in SDLC, a value must be passed in anyway.



Although set_protocol() completely ignores whatever value is passed in for parity in X75, a value must be passed in anyway.

set_protocol( )

The COPS protocol is used for character-oriented protocols. When COPS is specified, the set_sync, set_transtext, set_bcc and set_resync functions should be called to define other Setup Menu values. COPS also handles async protocols.

protocol	mode	datacode	parity	errorcheck
COPS	ASYNC_1	EBCDIC	NO_PARITY	NO_ERROR_CHECK
	ASYNC_1_5	ASCII8	ODD_PARITY	LRC
	ASYNC_2	ASCII7	EVEN_PARITY	CRC_6
	SYNC_DCE	HEX8	IGNORE	CRC_12
	SYNC_DTE	HEX7	NO_CHANGE	CRC_16
	NO_CHANGE	HEX6		NO_CHANGE
		HEX5		
		USER_DEF		
		NO_CHANGE		

BSC is a popular subset of COPS, but when it is used, the other Setup Menu values outlined in the description of COPS are automatically defined and the set_ functions do not need to be called.

protocol	mode	datacode	parity	errorcheck
BSC	SYNC_DCE	EBCDIC		CRC_16
	SYNC_DTE	ASCII7		LRC
	NO_CHANGE	USER_DEF		CRC_12
		NO_CHANGE		NO_CHANGE

Although set_protocol() completely ignores whatever value is passed in for parity in BSC, a value must be passed in anyway.

Return Values:

SUCCESSFUL (0)

set_protocol( )

WARNING_1 (1) One or more parameter values are unknown. Default value(s) used. See text for explanations of the default values.

ERROR_1 (-1) One or more parameter values are inconsistent. For example, this error would be returned if protocol==X25, datacode==ASCII8 and parity==ODD_PARITY, because this combination could not be created with the protocol analyzer's Setup Menu.

ERROR_10 (-10) The data link control hardware has already been started. The dlc hardware must be stopped by calling stop_data() before any changes can be made to the dlc configuration.

See Also:

get_protocol(), get_mode(), get_datacode(), get_parity(), get_errorcheck(), set_sync(), set_transtext(), set_bcc(), set_resync()

Example:

```
#include <dlib.include>
#include <retval.include>

main()
{
    int result;

    printf("Protocol parms set to X25, SYNC_DTE, ASCII8, NO_PARITY and CRC_CCITT");
    if((result = set_protocol(X25,SYNC_DTE,ASCII8,NO_PARITY,CRC_CCITT)) != SUCCESSFUL)
    {
        printf("Error #%d returned from set_protocol().\n",result);
        getch();
        exit();
    }
    getch();
}
```

set_resync()

Format:

```
#include <dlib.include>
#include <retval.include>

int set_resync(rmode, numafter, itext, otext1, otext2, otext3, otext4, otext5, otext6)
int rmode, numafter;
char itext, otext1, otext2, otext3, otext4, otext5, otext6;
```

Description:

Defines the protocol rules for resynching, that is, dropping sync on the data stream and ignoring data on the line until the sync pattern is found again. This function should only be used with a character-oriented protocol (COPS in set_protocol(), or Char Asyn/Syn in the protocol analyzer's Setup Menu) in synchronous mode (SYNC_DCE or SYNC_DTE in set_protocol(), or Sync in the Setup Menu).

When the resync mode parameter, rmode, is set to MANUAL, the protocol analyzer does not drop sync until resync() is called, at which time sync is dropped immediately, without regard to any other factors. All other parameters (numafter, itext, otext1-6) are ignored when rmode is MANUAL. If rmode is set to AUTO, resynching is done automatically based on the numafter, itext, and otext1 - otext6 parameters.

The numafter parameter can be set to any integer between (and including) zero and 99. It defines how many characters to wait after the block check character (bcc) is received before dropping sync.

The itext parameter is an 8-bit value that tells the data link control hardware what character to drop sync on while in the transparent text mode. See set_transtext() for more information on the transparent text mode.

The otext parameters (otext1 - otext6) form an array of six 8-bit values defining characters that the data link control hardware drops sync on while outside of the transparent text mode.

Library Functions

set_resync()

Return Values:

SUCCESSFUL (0)

WARNING_1 (1) The value of one or more of the parameter values is unknown. It is assumed to be the default. The mode parameter defaults to AUTO, numafter to 10, itext to 0x2d, and otext1, otext2, otext3, otext4, otext5 and otext6 to 0x2d, 0x37, 0x3d, 0x70, 0x7f and 0xff, respectively.

ERROR_1 (-1) The protocol is not COPS.

ERROR_2 (-2) The mode is not SYNC_DTE or SYNC_DCE.

ERROR_10 (-10) The protocol analyzer's data link control hardware was already running. The stop_data function must be called to halt the dlc hardware before any attempts to change the configuration.

See Also:

get_resyncafter(), get_resynchars(), get_resyncmode(), resync(), set_bcc(), set_protocol()

Library Functions

Example:

```
#include <dlib.include>
#include <retval.include>

main()
{
    int result;

    if((result = set_protocol(COPS,SYNC_DTE,NO_CHANGE,NO_CHANGE,NO_CHANGE))
                                                        != SUCCESSFUL)
    {
        printf("Error #%d returned from set_protocol().\n", result);
        getch();
        exit();
    }
    if((result = set_resync(AUTO,10,0x2d,0x2d,0x37,0x3d,0x70,0x7f,0xff)) != SUCCESSFUL)
    {
        printf("Error #%d returned from set_resync().\n", result);
        getch();
        exit();
    }
    getch();
}
```

set_rows()

Format:

```
void set_rows(min, max)
int min, max;
```

Description:

Sets the minimum and maximum rows to be written to using the screen output functions. This allows text to be confined to a certain area, or window, on the screen.

Return Values:

None

Example:

```
main()
{
    int i;

    set_rows(1, 10);
    for( i = 1; i < 20; i++)
        printf("This line will be displayed within rows 1 and 10.\n");
    getch();
}
```

set_screen_mode()

Format:

```
#include <video.include>

void set_screen_mode(scrn_mode)
int scrn_mode;
```

Description:

Sets the screen mode to show a normal display (scrn_mode = ASCII_DISPLAY), or a display where whitespace and other transparent characters are represented by special characters (scrn_mode = TRANSPARENT_DISPLAY) instead of producing editing effects. For example, in TRANSPARENT_DISPLAY, a linefeed character would create a L_F character instead of advancing the cursor to the next row of text.

Return Values:

None

Example:

```
#include <video.include>

main()
{
    set_screen_mode(TRANSPARENT_DISPLAY);
    printf("The new line '\n' characters in this string will be displayed.\n");
    getch();
}
```

set_stop_states( )

Format:

```
#include <leads.include>
#include <retval.include>

int set_stop_states(lead_id, stop_state)
unsigned long lead_id;
int stop_state;
```

Description:

Sets the stop states of the specified interface lead (clocks and control leads). Only the leads that belong to the channel configured as the transmitter (see `set_channelconfig()`) may be specified in this function.

Return Values:

`SUCCESSFUL (0)`

`WARNING_1 (1)` There was an error in compatibility between the `lead_id` and the `stop_state` type. Trying to set a `stop_state` of `ON` for a clock lead, for instance, produces this return code. The following assumptions are made in this case:

All clock leads:	`ON` is replaced by `MARKING` or `ACTIVE`.
All clock leads:	`OFF` is replaced by `NOT_DRIVEN`.
All control leads:	`MARKING` or `ACTIVE` is replaced by `ON`.
All control leads:	`NOT_DRIVEN` is replaced by `OFF`.

Data lead stop states may not be modified.

`ERROR_1 (-1)` The `stop_state` parameter value was invalid. No stop states were set.

`ERROR_2 (-2)` The lead's channel was not configured (using `set_channelconfig()`) for transmit or for `SIMULATE`. No stop states were set.

ERROR_10 (-10) The protocol analyzer's data link control hardware was already running. The stop_data function should be called to halt the dlc hardware before any attempt to change the configuration.

See Also:

get_stop_states(), set_channelconfig()

Example:

```
#include <dlib.include>
#include <leads.include>
#include <retval.include>

main()
{
    int result;

    if((result = set_stop_states(RTS | DTR, ON)) != SUCCESSFUL)
    {
        printf("Error #%d returned from set_stop_states().\n",result);
        getch();
        exit();
    }
    getch();
}
```

set_sync()

Format:

```
#include <dlib.include>
#include <retval.include>

int set_sync(sync_mode, synchar1, synchar2)
int sync_mode;
char synchar1, synchar2;
```

Description:

Sets the values of the sync characters and the synchronizaton mode. This function should only be used with a character-oriented protocol (COPS in set_protocol(), or **Char Asyn/Syn** in the protocol analyzer's Setup Menu) in synchronous mode (SYNC_DCE or SYNC_DTE in set_protocol(), or **Sync** in the Setup Menu).

The DataCommC event formatter uses sync character framing to create events from the data stream. When sync characters are not defined, the event formatter treats each character as an event, which significantly reduces system performance.

The sync_mode parameter may be set to ON or OFF (these constant values are located in the dlib.include file). If sync_mode is ON, the synchar1 and synchar2 parameters are used to define event framing. If sync_mode is OFF, the data are treated as if they are asynchronous, unframed characters, synchar1 and synchar2 are ignored, and every character forms an event.

The synchar1 and synchar2 parameters are 8-bit values that are passed to the data link control hardware when the start_data() is called. Datacode and parity (see set_protocol()) choices do not affect already-established synchar values.

Return Values:

SUCCESSFUL (0)

WARNING_1 (1) The value of one or more of the parameter values is unknown. It is assumed to be the default. The sync_mode parameter defaults to ON, and both synchars default to 0x16.

ERROR_1 (-1) The protocol is not COPS.

ERROR_2 (-2) The mode is not SYNC_DTE or SYNC_DCE (see set_protocol()).

ERROR_10 (-10) The protocol analyzer's data link control hardware was already running. The stop_data function should be called to halt the dlc hardware before any attempt to change the configuration.

See Also:

get_synchars(), set_resync(), set_protocol()

Example:

```
#include <dlib.include>
#include <retval.include>

main()
{
    int result;

    printf("Testing the set_sync function.");
    if((result = set_sync(ON, 0x32, 0x32)) != SUCCESSFUL)
    {
        printf("Error #%d returned from set_sync().\n", result);
        getch();
        exit();
    }
    getch();
}
```

set_time()

Format:

```
#include <time.include>

void set_time(time)
struct tm *time;
```

Description:

Sets the current system time. When the address of an updated copy of the tm structure (pointed to by the time parameter) is passed to this function, the modified blocks in the structure are used to reprogram the real-time-clock. The tm data structure is defined in the time.include file (see chapter 4, "Include Files", for more information), and is outlined below.

struct tm

Type	Field	Description
int	tm_msecs	0-900 milliseconds after the second (100 msec intervals)
int	tm_sec	0-59 seconds after the minute
int	tm_min	0-59 minutes after the hour
int	tm_hour	0-23 hours after midnight
int	tm_day	1-31 days of the month
int	tm_mon	1-12 months of the year
int	tm_year	0-99 years after turn of century

Return Values:

None

set_time()

See Also:

get_time()

Example:

```
#include <time.include>

main()
{
   struct tm time;

   get_time(&time);
   printf("The date is %d/%d/%d and the old time is %d:%d:%d.%d.",
      time.tm_mon,
      time.tm_day,
      time.tm_year,
      time.tm_hour,
      time.tm_min,
      time.tm_sec,
      time.tm_msecs );

   time.tm_hour = 6;
   set_time(&time);
   get_time(&time);
   printf("The date is %d/%d/%d and the new time is %d:%d:%d.%d.",
      time.tm_mon,
      time.tm_day,
      time.tm_year,
      time.tm_hour,
      time.tm_min,
      time.tm_sec,
      time.tm_msecs );
   getch();
}
```

set_timer()

Format:

```
int set_timer(number_of_tenths)
unsigned long number_of_tenths;
```

Description:

Sets one of the DataCommC timers for the duration, in tenths of seconds, specified in the number_of_tenths parameter.

Return Values:

Returns the number of the timer set (a non-negative integer), or

-1 if there is no memory for the timer, or if there are already 32,767 timers active. The request is ignored.

-2 if number_of_tenths == 0.

See Also:

clear_timer(), wait()

Example:

```
#include <retval.include>
#include <message.include>
#define FOREVER 1

main()
{
    int timer_number, result;
    long timer_duration = 10; /* set timeout for 1 second */
    MESSAGE msg;

    printf("Attempting to set the timer....\n");
    if((result = set_timer(timer_duration)) < 0)
    {
        printf("Error #%d returned from set_timer().\n",result);
        getch();
        exit();
    }

    timer_number = result;
    while(FOREVER)
    {
        if(read_message(&msg,1,0l))
            printf("Error reading message queue.\n");
        else
        {
            if((msg.type == TIMER) && (msg.subtype == TIMER_TIMEOUT))
                if(msg.body.timer_message.timer_number == timer_number)
                {
                    printf("Timer %d has expired.\n", timer_number);
                    break;
                }
        }
    }
    getch();
}
```

set_transtext()

Format:

```
#include <dlib.include>
#include <retval.include>

int set_transtext(trans_mode, ttextchar)
int trans_mode;
char ttextchar;
```

Description:

Defines the protocol rules for transparent text mode when the protocol is COPS.

When the transparent text mode parameter, trans_mode, is OFF, transparent text characters are not recognized. If trans_mode is ON, the 8-bit value specified in ttextchar is used to signal a break into or out of the transparent text mode. While in transparent mode, all control characters are treated as data, that is, their defined control functions are not executed.

As mentioned above, the transparent text character, ttextchar, is an 8-bit value that defines the boundaries of the transparent text mode. It signals both the beginning and the end of the transparent text mode.

Return Values:

SUCCESSFUL (0)

WARNING_1 (1)	The value of one or more of the parameter values is unknown. It is assumed to be the default. The trans_mode parameter defaults to OFF, in which case ttextchar is ignored. If trans_mode==ON, ttextchar may default to 0x10 (in ASCII, DLE - data link escape character).
ERROR_1 (-1)	The protocol is not COPS.

ERROR_10 (-10) The protocol analyzer's data link control hardware was already running. The stop_data function must be called to halt the dlc hardware before any attempt to change the configuration.

See Also:

get_transtext()

Example:

```
#include <dlib.include>
#include <ascii.include>
#include <retval.include>

main()
{
    int result;

    if((result = set_transtext(ON,as_DLE)) != SUCCESSFUL)
    {
        printf("Error #%d returned from set_transtext().\n",result);
        getch();
        exit();
    }
    getch();
}
```

setjmp( )

Format:

```
#include <setjmp.include>

int setjmp(env)
jmp_buf env;
```

Description:

Saves the stack environment values in the memory block indicated by `env`, so that they may later be restored by `longjmp()`. The `longjmp` and `setjmp` functions are useful for dealing with errors encountered by the low-level functions of a program.

Return Values:

If `setjmp()` returns by way of a `longjmp()` call, it returns the `val` argument passed to `longjmp()`. Otherwise it returns zero.

See Also:

`longjmp()`

Example:

```
#include <setjmp.include>

main()
{
   jmp_buf buff;

   printf("We are about to call setjmp.\n");
   printf("Please hit any character to call it.\n");
   getch();
   if(setjmp(buff))
   {
      printf("We are in the if clause.\n");
      printf("We should have had an error and will return.\n");
   }
   else
   {
      printf("We are executing the else clause.\n");
      printf("We are now pretending to have an error.\n");
      printf("Hit any key to have a fake error and call longjmp.\n");
      getch();
      longjmp(buff,-1);
      printf("We have just called longjmp.  This should never get printed.\n");
   }
   printf("Please hit any key to return.\n");
   getch();
}
```

sin()

Format:

```
#include <math.include>

double sin(x)
double x;
```

Description:

Calculates the sin of the angle x (where x is expressed in radians).

Return Values:

Returns the sine of x.

See Also:

```
asin(), atan(), atan2(), acos(), cos(), cosh(), cotan(), sinh(), tan(), tanh()
```

Example:

```
#include <math.include>
#define PI 3.141592654

main()
{
    double y, radx = PI/2;

    y = sin(radx);
    printf("The sine of PI/2 is %f.", y);
    getch();
}
```

sinh( )

Format:

```
#include <math.include>

double sinh(x)
double x;
```

Description:

Calculates the hyperbolic sin of x.

Return Values:

Returns the hyperbolic sine of x.

See Also:

`asin(), atan(), atan2(), acos(), cos(), cosh(), cotan(), sin(), tan(), tanh()`

Example:

```
#include <math.include>
#define PI 3.141592654

main()
{
   double y, radx = PI/2;

   y = sinh(radx);
   printf("The hyperbolic sine of PI/2 is %f.", y);
   getch();
}
```

spawn()

Format:

```
#include <system.include>
#include <retval.include>

int spawn(path_name, number_of_user_args, user_args, priority, child_QID)
char *path_name;
int number_of_user_args;
char *user_args[];
int priority;
long *child_QID;
```

Description:

Creates a process that can execute independently of the calling process. The child process is spawned using system defaults and should be given a priority number between 1 and 199. If the priority is not within this range, `priority` is set to `DEFAULT_PRIORITY`, which is defined in the `system.include` file to be 100.

When the function returns successfully, the child's queue number is placed in the memory location pointed to by `child_QID`.

Null-terminated character strings can be passed to any spawned child process through the `number_of_user_args` and `user_args` arguments. The child process can gain access to these arguments through the `argc` and `argv` parameters of its own `main` function. Information from `number_of_user_args` is passed to `argc`, and information from `user_args` is passed to `argv`.

The `argc` parameter in `main()` is always greater than or equal to 1 because the run-time system inserts the child's path name into `argv[0]`. If the parent process passes a pointer to a string in `user_args[0]`, the child would use the element `argv[1]` to get a pointer to the string in the child's memory space.

Return Values:

`SUCCESSFUL (0)` A child process was spawned.

-1	The program prog_name was not found.
-2	There was no memory for the child process.
-3	Invalid program file format found.
-15 to -19	Can't communicate with ROOT process.
-21	No message queues were available.
-22	Can't notify process manager.
-41	Too many processes.
-42	No memory for user stack.
-43	User stack was too small.

See Also:

exit()

spawn()

Example:

```
#include <retval.include>
#include <system.include>

main()
{
    int result, number_of_child_args = 2;
    char *argv[2];
    long child_qid;
    char input[81];
    char output[81];

    /* set up arguments to pass to child process */
    printf("Enter input file for child process:");
    gets(input);
    argv[0] = input;

    printf("Enter output file for child process:");
    gets(output);
    argv[1] = output;
    if((result = spawn("c:userprog.program",number_of_child_args,argv,
                           DEFAULT_PRIORITY, &child_qid)) != SUCCESSFUL)
    {
        printf("Error #%d returned from spawn().\n",result);
        getch();
        exit();
    }
    printf("The QID of the child_process is %lx.\n",child_qid);
    getch();
}
```

spawnw( )

Format:

```
#include <system.include>
#include <retval.include>

int spawnw(path_name, number_of_user_args, user_args, priority, child_exit_value)
char *path_name;
int number_of_user_args;
char *user_args[];
int priority;
int *child_exit_value;
```

Description:

Creates a process that can execute independently of the calling process. The child process is spawned using system defaults and should be given a priority number between 1 and 199. If the priority is not within this range, `priority` is set to `DEFAULT_PRIORITY`, defined to be 100.

If the child is successfully spawned, the calling process is blocked until the child process terminates using the `exit` function. After program execution is returned to the parent process, the `child_exit_value` parameter points to the integer value that the child specified when it called `exit()` (for example, `exit(0)`;). If the child calls `exit()` without specifying an exit value, zero is returned to the parent through `child_exit_value`.

Null-terminated character strings can be passed to any spawned child process through the `number_of_user_args` and `user_args` arguments. The child process can gain access to these arguments through the `argc` and `argv` parameters of its own `main` function. Information from `number_of_user_args` is passed to `argc`, and information from `user_args` is passed to `argv`.

The `argc` parameter in `main()` is always greater than or equal to 1 because the run-time system inserts the child's path name into `argv[0]`. If the parent process passes a pointer to a string in `user_args[0]`, the child would use the element `argv[1]` to get a pointer to the string in the child's memory space.

Library Functions

spawnw()

Return Values:

SUCCESSFUL (0)	A child process was spawned.
-1	The program prog_name was not found.
-2	There was no memory for the child process.
-3	Invalid program file format found.
-15 to -19	Can't communicate with ROOT process.
-21	No message queues were available.
-22	Can't notify process manager.
-41	Too many processes.
-42	No memory for user stack.
-43	User stack was too small.

exit()

Example:

```
#include <retval.include>
#include <system.include>

main()
{
   int result, number_of_child_args = 2;
   char *argv[2];
   int child_exit_value;
   char input[81];
   char output[81];

   /* set up arguments to pass to child process */
   printf("Enter input file for child process:");
   gets(input);
   argv[0] = input;

   printf("Enter output file for child process:");
   gets(output);
   argv[1] = output;
   if((result = spawnw("c:userprog.program",number_of_child_args,argv,
                              DEFAULT_PRIORITY, &child_exit_value)) != SUCCESSFUL)
   {
      printf("Error #%d returned from spawn().\n",result);
      getch();
      exit();
   }
   printf("The child's exit value is %lx.\n",child_exit_value);
   getch();
}
```

sprintf( )

Format:

```
sprintf(str,format,args)
char *str;
char *format;
char *args;
```

Description:

Outputs or prints arguments in `args` to a memory location pointed to by `str` according to `format`.

The character string pointed at by `format` directs the output operation, and contains two types of information: ordinary alphanumeric characters, which are output unchanged; and conversion specifications, each of which causes the conversion and output of the next argument in the `args` list.

The formatted string is output from left to right. When a conversion specification is encountered, the next (initially first) argument is output according to the conversion specification.

A conversion specification has the form:

```
%[flag][width][.precision][l]type
```

Each field enclosed in braces "[ ]" is optional and consists of a single character or number signifying a particular format option.

Library Functions

`flag`

- The converted argument is left-justified when printed. The default is right-justification.

`width`

digit string The numeric digit string specifies the field width for the conversion. If the converted value has fewer characters than `width`, enough blank (space) characters are output to make the total number of characters output equal the field width. The spaces are output before or after the value, depending on the presence or absence of the left-justification flag. If the field width digits have a leading zero, zeros are used as pad characters instead of spaces. If the converted string has more characters than the value of `width`, the string is truncated.

* The `width` parameter is supplied by the corresponding argument in the argument list (`args`). The argument must be of type `int`.

`.precision`

digit string For floating point conversions, `precision` specifies the number of digits to appear after the decimal point; for character string conversions, it specifies the maximum number of characters to be printed from a string.

* The `precision` parameter is supplied by the corresponding argument in the argument list (`args`). The argument must be of type `int`.

`l`

A conversion normally performed on an `int` is performed on a `long` (may be used with the `d`, `o` and `x` conversion characters).

sprintf( )

The type character format is as follows:

character	type of argument	output format
d	int	signed decimal
u	int	unsigned decimal
x	int	unsigned hexadecimal
o	int	unsigned octal
f	float or double	floating point
c	char	single character
s	string	character string
e	float or double	scientific nototation
g	uses d, f or e - whichever gives full precision in minimum space	

Return Values:

Returns the number of characters in str, not including the terminating NULL.

See Also:

printf(), fprintf()

Example:

```
main()
{
    int j = 1;
    char outbuf[80];

    sprintf(outbuf,"The integer in hex is %x.\n",j);
    puts(outbuf);
    getch();
}
```

sqrt( )

Format:

```
#include <math.include>

double sqrt(x)
double x;
```

Description:

Calculates the square root of x.

Return Values:

Returns the result of the square root operation.

See Also:

```
exp(), log(), pow()
```

Example:

```
#include <math.include>

main()
{
   double x,y;

   x = 9;
   y = sqrt(x);
   printf("The square root of %3.1f = %3.1f.\n",x,y);
   getch();
}
```

Library Functions

srand( )

Format:

```
void srand(val)
int val;
```

Description:

Sets the seed of the pseudo-random number generator.

Return Values:

None

See Also:

```
rand()
```

Example:

```
main()
{
    unsigned i = 50;

    printf("Setting the random number generator seed to 50.");
    srand(i);
    getch();
}
```

sscanf( )

Format:

```
int sscanf(buffer, format, args)
char *buffer;
char *format;
char *args;
```

Description:

Takes text characters from the specified buffer or string (buffer), checks the character types against conversion characters imbedded in a control string pointed to by the format parameter, and places matching text in the fields pointed to by the args list.

The following sscanf() example shows the main components of the function:

```
sscanf(scanbuf, "%f%s", &fltptr, &strptr);
```

The string "%f%s" is a control string (format) with two control items (both conversion characters), one indicating a floating point value (%f), and the other (%s) indicating a string. The other arguments, &fltptr and &strptr, define the argument list (args). If sscanf() finds floating point characters, it places them in the memory location pointed to by fltptr; if a character string is found next, it is placed in the memory location pointed to by strptr.

A control string contains these control items:

- Conversion specifications
- Optional white space characters (tab, space, newline)
- Optional alphanumeric characters (not white space, and not part of a conversion specification).

The sscanf function works its way through a control string from left to right, trying to match each control item to a portion of the input stream. During the matching process, sscanf() fetches characters one at a time from the input stream. If a character is found which doesn't match the type specifier for the corresponding conversion specification, sscanf() pushes the character back onto the input stream and finishes processing the current control item. This

sscanf( )

"pushing back" frequently gives unexpected results when a stream is used later by other I/O functions, such as `getc()` or `scanf()`, as well as by `sscanf()` itself, if it is used again.

A conversion specification has the form:

```
%[*][width][l]type
```

Each field enclosed in braces "`[ ]`" is optional and consists of a single character or number signifying a particular format option. The simplest possible conversion specification contains a percent sign (`%`) and a conversion character (ex: `%f`)

The optional fields are defined below, and conversion characters are discussed later in this segment.

`*`
: Assignment suppression character. The current stream is scanned, but not saved. The function goes on to the next control string item.

`width`
: This field specifies the maximum number of characters to be fetched for the conversion.

`l`
: This field indicates that the argument is a pointer to a long data type - the exact type (for example, long decimal, long hex, long unsigned) is determined by the conversion character.

The conversion character format is as follows:

character	type of argument	expected input format
d	pointer to int	signed decimal
u	pointer to int	unsigned decimal
x	pointer to int	unsigned hexadecimal
o	pointer to int	unsigned octal
e,f	pointer to float	floating point
c	pointer to char	single character
s	pointer to char array	character string

When a conversion specification is encountered in the control string, the `sscanf` function skips leading white space on the input stream, then collects characters from the stream until it encounters one that is not appropriate for the corresponding conversion character. That character is pushed back onto the input string.

As long as the conversion specification didn't request assignment suppression (see '*', above), the text string that was read from the keyboard is converted to the format specified by the conversion specification, the result is placed in the location pointed to by the corresponding args argument, the next argument becomes current, and the function proceeds to the next control string item.

If assignment suppression was requested, the `sscanf` function ignores the input characters and goes on the next control item.

If an ordinary character is found in the control string, outside any conversion specification, `sscanf()` fetches the next character. If that character matches the character in the control string, the function goes on to the next control string item, ignoring the input character. If there is no match, `sscanf()` terminates.

If a white space character is found in the control string, the `sscanf` function fetches input characters until the first non-white space character is read. The non-white space character is pushed back onto the input stream and `sscanf()` proceeds to the next item in the control string.

sscanf( )

Return Values:

Returns the number of items converted and assigned to memory locations in args. Unmatched items, since they are not assigned to args, are not included in the count.

See Also:

scanf(), fscanf()

Example:

```
main()
{
    int i;
    char *scanfbuf;

    scanfbuf = "100";
    sscanf(scanfbuf,"%d", &i);
    printf("The integer i = %d.\n",i);
    getch();
}
```

start_data()

Format:

```
#include <retval.include>

int start_data()
```

Description:

Activates the protocol analyzer's data link control hardware and starts data aquisition. The source of data defaults to the protocol analyzer's setup value unless it has been changed with the set_data_source function. When start_data() runs, the contents of the data buffer are flushed, and events formed from the incoming data are put into the process queue. Leads, however, are not affected. Any of the leads that have been left in a stop state (with set_stop_states()) remain in that state after data aquisition ends.

If the source of data has been set to DISC_RUN, set_data_source() must be called before each start_data() call.

Return Values:

SUCCESSFUL (0)

ERROR_1 (-1)	There was an error in opening the data file.
ERROR_2 (-2)	The function encountered an unrecognized data link control data source (This error would only occur if the program's external data had been overwritten).
ERROR_5 (-5)	A fatal error occurred during an attempt to communicate with the dlc hardware.
ERROR_9 (-9)	There was no pod, or an unrecognized pod was attached to the protocol analyzer.
ERROR_10 (-10)	The dlc was already running.

ERROR_100 (-100) The protocol was not implemented.

stop_data(), set_stop_states(), set_data_source()

Example:

```
#include <message.include>
#include <retval.include>

main()
{
   MESSAGE msg;
   int result;

   if((result = start_data()) != SUCCESSFUL)
   {
      printf("Data Transmit/Receive cannot be started - error # %d.",result);
      exit();
   }
   read_message(&msg, WAIT, WAIT_FOREVER);
   stop_data();
   printf("The message type read is: %d\n",msg.type);
   getch();
}
```

start_display( )

Format:

```
int start_display(file, screen_size, share_keyboard)
char *file;
int screen_size;
int share_keyboard;
```

Description:

Spawns a run-time procotol display. Only one display process may be active at a time. The display process is always given a priority (priority level 2) lower than any user process

The `file` parameter is the full path name of the desired protocol display program. The `c:C/Decode/BOPS.program` run-time display program is included with the DataCommC package. The display program may reside in any directory on the hard disc or on a flexible disc, but if a NULL character is passed to the file parameter, the default display is used, that is, the program that was chosen to be the default in the DataCommC Buffer Manager Menu.

A DataCommC program may share the screen with a display program by having the display program confine itself to a certain region of the screen. Although the display program's screen area always starts at the top of the screen, you can use the `screen_size` parameter to determine how many rows of the screen the display process may use. The `screen_size` parameter has a minumum value of 3 and a maximum value of 21 rows. The screen area cannot be less than 3 because the display process needs one row for its column heading, one for the line that shows the bottom of its screen area, and the third to display data. If `screen_size` is less than 3 or greater than 21, the display process uses the entire screen (21 rows plus the softkey area) and issues no warnings. The display process's softkey area is the bottom four rows of the screen.

If `share_keyboard` is `FALSE` (0), the display process generates a **Stop Run** softkey in the erightmost position (`SK8`), and when it is pressed, the display process exits (terminates itself) and notifies its parent process (your program) by sending it a message of type `DISPLAY` and subtype `STOPPED` (see `read_message()` and the include file `message.include`). Note that the display process does not stop the run; it is up to your program to do that when it receives the `DISPLAY/STOPPED` message.

Library Functions

start_display( )

In most cases, the display would be spawned with share_keyboard equal to FALSE, and a screen_size of 21 (the entire screen).

Normally your program would not be able to receive input from the keyboard while a protocol display process is running, since all keyboard input goes to that process. If, however, you start the display process with a share_keyboard parameter of TRUE (1), your program and the display process may pass control of the keyboard back and forth.

If share_keyboard is TRUE, the display process begins in its keyboard-off state, that is, it does not attempt to read input from the keyboard and refrains from writing to the softkey area of the screen. Your program begins with control of the keyboard and the softkey area. A "best practice" is to paint whatever softkeys are needed for your application, as well as one labeled Display Control, and then use a loop on getch() to handle keyboard inputs.

When your program detects that its Display Control softkey has been pressed, it should call keyboard_unlock() to give up control of the keyboard, and display_keys_on() to notify the display process that it now has control of the keyboard and softkey area. At this point, your program should refrain from calling getch() or writing to the softkey area, and should wait until the display process sends notification that it has relinquished control of the keyboard. This notification comes in the form of a message of type DISPLAY and subtype KEYBOARD_OFF which is generated when the display process's top level Exit softkey is pressed (when the keyboard is shared, the display process generates Exit instead of the Stop Run softkey).

Once this notification is received, your program should call keyboard_lock() to retake control of the keyboard, redisplay its softkeys, and continue looping on getch(). For an example of this type of program, see display_keys_on().

Return Values:

0 The display process was successfully spawned.

-1 The specified display program (file) was not found, or if file was NULL, the current default decode was not found.

-2 There wasn't enough memory for the display process.

-3	The specified program (file) was not a valid program.
-15 to -19	The function couldn't communicate with the ROOT process.
-21	There weren't any message queues available.
-22	The function couldn't notify the process manager.
-41	There were too many processes active.
-42	There wasn't any memory for the user stack.
-43	The user stack was too small.
-100	Another display process was already active.

See Also:

`stop_display()`

start_display()

Example:

```
#include <stdio.include>
#include <message.include>
#include <retval.include>

main()
{
    MESSAGE msg;
    int done, result;

    set_rows(17,21);
    result = start_display(NULL, 15, 0);
    printf("start_display() returned %d\n", result);
    done = 0;
    while(!done)
    {
        if(read_message(&msg, WAIT, WAIT_FOREVER) = SUCCESSFUL)
            if((msg.type == DISPLAY) && (msg.subtype == STOPPED))
            {
                done = 1;
                stop_display();
            }
    }
}
```

stop_data()

Format:

```
int stop_data()
```

Description:

Halts the protocol analyzer's data link control hardware and stops data aquisition and event formation. Leads are left in the state previously defined in `set_stop_states()`. If the data source had been set to `DISC_RUN` (see `set_data_source()`), the data file is closed.

Return Values:

`SUCCESSFUL (0)`

`ERROR_1 (-1)` The data link control hardware was not running when `stop_data()` was called.

See Also:

`start_data()`

stop_data()

Example:

```
#include <message.include>
#include <retval.include>

main()
{
   MESSAGE msg;
   int result;

   if((result = start_data()) != SUCCESSFUL)
      {
      printf("Data Transmit/Receive cannot be started - error # %d.", result);
      exit();
      }
   read_message(&msg, WAIT, WAIT_FOREVER);
   stop_data();
   printf("The message type read is: %d\n", msg.type);
   getch();
}
```

Library Functions

stop_display()

Format:

```
int stop_display()
```

Description:

Terminates execution of the Run-time Display (decode) process.

Return Values:

0	The exit message was sent.
-1	The queue has been deleted
-2	An invalid queue number was given.
-3	Out of memory.
-5	Out of memory.
-6	The queue was full.

See Also:

```
start_display()
```

stop_display()

Example:

```
#include <stdio.include>
#include <message.include>
#include <retval.include>

main()
{
    MESSAGE msg;
    int done, result;

    set_rows(17,21);
    result = start_display(NULL, 15, 0);
    printf("start_display() returned %d\n", result);
    done = 0;
    while(!done)
    {
        if(read_message(&msg, WAIT, WAIT_FOREVER) = SUCCESSFUL)
            if((msg.type == DISPLAY) && (msg.subtype == STOPPED))
            {
                done = 1;
                stop_display();
            }
    }
}
```

strcat( )

Format:

```
#include <string.include>

strcat(s2,s1)
char *s2;
char *s1;
```

Description:

Copies, or concatenates, s1 onto the end of s2 (does not test for s2 overflow).

Return Values:

None

See Also:

```
strncat()
```

Example:

```
#include <string.include>

main()
{
   char buf[30];

   strcpy(buf,"hello");
   strcat(buf," world");
   puts(buf);
   getch();
}
```

Library Functions

strchr( )

Format:

```
#include <string.include>

char *strchr(str,ch)
char *str;
char ch;
```

Description:

Returns a pointer to the first occurrence of character `ch` in string `str`, or `NULL` if not found (works even if `ch = NULL`). Use `strrchr()` to find the last occurrence of `ch` in `str`.

Return Values:

The return value is described above.

See Also:

```
strrchr()
```

Example:

```
#include <string.include>
main()
{
   char *buf, *substr;

   buf = "hello world";
   substr = strchr(buf,'w');
   printf("The remaining string is %s.\n",substr);
   getch();
}
```

strcmp( )

Format:

```
int strcmp(str1,str2)
char *str1;
char *str2;
```

Description:

Compares strings `str1` and `str2`. Returns a negative number if `str1 < str2`, zero if `str1 = str2`, and a positive number if `str1 > str2`. Uses a lexicographic comparison.

Return Values:

The return value is described above.

See Also:

```
strcmpi(), strncmp()
```

strcmp( )

Example:

```
main()
{
    char *str1, *str2;
    int result;

    str1 = "hello world";
    str2 = "hello World";
    if((result = strcmp(str1,str2)) < 0)
       printf("str1 < str2");
    else if (result == 0)
       printf("The two strings are equal");
    else
       printf("str1 > str2 ");
    getch();
}
```

strcmpi( )

Format:

```
int strcmpi(str1,str2)
char *str1;
char *str2;
```

Description:

Compares strings str1 and str2. Returns a negative number if str1 < str2, zero if str1 = str2, and a positive number if str1 > str2. This routine is independent of case (upper or lower), and uses lexicographic comparison.

Return Values:

The return value is described above.

See Also:

strcmp()

Library Functions

strcmpi( )

Example:

```
main()
{
   char *str1, *str2;
   int result;

   str1 = "hello world";
   str2 = "hello World";
   if((result = strcmpi(str1,str2)) < 0)
      printf("str1 < str2");
   else if (result == 0)
      printf("The two strings are equal");
   else
      printf("str1 > str2 ");
   getch();
}
```

strcpy( )

Format:

```
#include <string.include>

char *strcpy(s2, s1)
char *s2;
char *s1;
```

Description:

Copies `s1` to `s2` up to and including the terminating `NULL` character.

Return Values:

Returns a pointer to `s2`.

See Also:

```
strncpy()
```

Example:

```
main()
{
    char buf[30];

    strcpy(buf,"hello world");
    puts(buf);
    getch();
}
```

Library Functions

strlen( )

Format:

```
int strlen(str)
char *str;
```

Description:

Finds the length of the string, `str` (strings are terminated by a `NULL` character).

Return Values:

Returns the string length.

Example:

```
#include <string.include>

main()
{
   char buf[30];
   int length;

   strcpy(buf,"hello world");
   length = strlen(buf);
   printf("The length of 'buf' is %d.\n", length);
   getch();
}
```

strncat( )

Format:

```
#include <string.include>

char *strncat(s2,s1,n)
char *s2;
char *s1;
int n;
```

Description:

Copies n characters (maximum) from s1 onto the end of s2.

Return Values:

Returns a pointer to s2.

See Also:

```
strcat()
```

Library Functions

strncat( )

Example:

```
#include <string.include>

main()
{
    char buf1[30], *buf2;

    strcpy(buf1,"hello ");
    buf2 = "world";
    strncat(buf1,buf2,strlen(buf2));
    puts(buf1);
    getch();
}
```

Library Functions

strncmp( )

Format:

```
int strncmp(str1,str2,n)
char *str1;
char *str2;
int n;
```

Description:

Compares the first `n` characters of `str1` and `str2`. Returns a negative number if `str1 < str2`, zero if `str1 = str2`, and a positive number if `str1 > str2`. Uses a lexicographic comparison.

Return Values:

The return value is described above.

See Also:

```
strcmp()
```

strncmp( )

Example:

```
main()
{
   char *str1, *str2;
   int result;

   str1 = "hello world";
   str2 = "hello World";
   if((result = strncmp(str1,str2,5)) < 0)
      printf("str1 < str2");
   else if (result == 0)
      printf("The two strings are equal");
   else
      printf("str1 > str2 ");
   getch();
}
```

strncpy( )

Format:

```
#include <string.include>

char *strncpy(str2,str1,n)
char *str1;
char *str2;
int n;
```

Description:

Copies n characters from str1 to str2. If str1 contains fewer than n characters, str2 is padded with NULLs. If there are more than n characters in str1, only the first n characters are copied into str2, and the resulting string is not null-terminated.

Return Values:

Returns a pointer to str2.

See Also:

strcpy()

Library Functions

strncpy( )

Example:

```
#include <string.include>

main()
{
   char buf[30];

   strcpy(buf,"hello world",6);
   puts(buf);
   getch();
}
```

Library Functions

strrchr( )

Format:

```
#include <string.include>

char *strrchr(str,ch)
char *str;
char ch;
```

Description:

Returns a pointer to the last occurrence of character `ch` in string `str`, or `NULL` if not found (this works even if `ch = NULL`). Use `strchr()` to find the first occurrence of `ch` in `str`.

Return Values:

The return value is described above.

See Also:

```
strchr()
```

strrchr( )

Example:

```
#include <string.include>

main()
{
    char *buf, *substr;

    buf = "hello world";
    substr = strrchr(buf,'w');
    printf("The remaining string is %s.\n",substr);
    getch();
}
```

strsave( )

Format:

```
#include <string.include>

char *strsave(str)
char *str;
```

Description:

Allocates enough memory to hold the string pointed to by `str`, copies `str` into it, and returns a pointer to the new copy.

Return Values:

Returns a pointer to the new copy of the string, or `NULL` if there was no memory for `strsave()` to allocate.

Example:

```
#include <string.include>

main()
{
   char *buf;

   buf = strsave("hello world");
   puts(buf);
   getch();
}
```

strtrm( )

Format:

```
#include <string.include>

char *strtrm(string)
char *string;
```

Description:

Trims trailing spaces from a string.

Return Values:

Returns a pointer to `string`.

Example:

```
#include <string.include>

main()
{
   char str[30];

   strcpy(str,"hello world        ");
   strtrm(str);
   printf("The string equals %s.",str);
   getch();
}
```

Library Functions

sys_msg()

Format:

```
void sys_msg(string)
char *string;
```

Description:

Writes the given string (`string`) to the screen (padded on either side with spaces to center it) with the current video attributes. This takes the whole row. Only the first 80 characters are written if the string is too long.

The cursor position is preserved.

Return Values:

None

Example:

```
main()
{

    sys_msg("This screen will be deleted when a key is pressed");
    getch();
}
```

tan( )

Format:

```
#include <math.include>

double tan(x)
double x;
```

Description:

Calculates the tangent of x (where x is expressed in radians).

Return Values:

Returns the tangent of x.

See Also:

asin(), atan(), atan2(), acos(), cos(), cosh(), cotan(), sin(), sinh(), tanh()

Example:

```
#include <math.include>
#define PI 3.141592654

main()
{
   double y, radx = PI/3;

   y = tan(radx);
   printf("The tangent of %f is %f.", radx, y);
   getch();
}
```

tanh( )

Format:

```
#include <math.include>

double tanh(x)
double x;
```

Description:

Calculates the hyperbolic tangent of x.

Return Values:

Returns the hyperbolic tangent of x.

See Also:

asin(), atan(), atan2(), acos(), cos(), cosh(), cotan(), sin(), sinh(), tan()

Example:

```
#include <math.include>
#define PI 3.141592654

main()
{
   double y, radx = PI/3;

   y = tanh(radx);
   printf("The hyperbolic tangent of %f is %f.", radx, y);
   getch();
}
```

toascii( )

Format:

```
#include <ctype.include>

int toascii(c)
char c;
```

Description:

Converts a single character, represented by the c parameter, to an ASCII character. The high-order bit of c is set to zero, converting the value to a valid member of the ASCII character set. If c was already an ASCII character, it remains unchanged.

Return Values:

Returns the character c.

See Also:

isalnum(), isalpha(), isascii(), iscntrl(), isdigit(), isgraph(), islower(), isprint(), ispunct(), isspace,(), isupper(), isxdigit(), tolower(), toupper()

toascii( )

Example:

```
#include <ctype.include>

main()
{
   char ch;

   ch = 0x95;
   ch = toascii(ch);
   printf("The ascii character is %c",ch);
   getch();
}
```

Library Functions

tolower()

Format:

```
#include <ctype.include>

int tolower(c)
char c;
```

Description:

Converts c to lowercase if c is uppercase.

Return Values:

Returns the lowercase version of the character c.

See Also:

isalnum(), isalpha(), isascii(), iscntrl(), isdigit(), isgraph(), islower(), isprint(), ispunct(), isspace,(), isupper(), isxdigit(), toascii(), toupper()

Library Functions

Example:

```
#include <ctype.include>
#include <stdio.include>

main()
{
    char ch;

    printf("Enter a character string for conversion - press RESET when done.\n");
    while(1)
    {
        ch = getc(stdin);
        if(isalpha(ch))
            switch(isupper(ch))
            {
                case 0:
                    printf("The character converted to upper case is '%c'.\n",toupper(ch));
                    break;
                default:
                    printf("The character converted to lower case is '%c'.\n",tolower(ch));
                    break;
            }
    }
}
```

toupper()

Format:

```
#include <ctype.include>

int toupper(c)
char c;
```

Description:

Converts `c` to uppercase if `c` is an lowercase letter.

Return Values:

Returns the uppercase version of the character `c`.

See Also:

`isalnum(), isalpha(), isascii(), iscntrl(), isdigit(), isgraph(), islower(), isprint(), ispunct(), isspace,(), isupper(), isxdigit(), toascii(), tolower()`

Example:

```
#include <ctype.include>
#include <stdio.include>

main()
{
    char ch;

    printf("Enter a character string for conversion - press RESET when done.\n");
    while(1)
    {
        ch = getc(stdin);
        if(isalpha(ch))
            switch(isupper(ch))
            {
                case 0:
                    printf("The character converted to upper case is '%c'.\n",toupper(ch));
                    break;
                default:
                    printf("The character converted to lower case is '%c'.\n",tolower(ch));
                    break;
            }
    }
}
```

trigger_on_message()

Format:

```
#include <message.include>

int trigger_on_message(message)
MESSAGE *message;
```

Description:

This routine reads (and blocks if necessary) messages from the process queue indicated by `message` and returns when one of the following conditions is met:

1) The message that was read has a message type and subtype that have been initialized as triggers in `init_trigger()`.

2) The message read has a subtype > 127 (negative). The `trigger_on_message` function returns on any subtype greater than 127. These subtypes are always initialized as triggers.

`DATACOMM` messages that do not cause `trigger_on_message()` to return are automatically released throught a call to `release_event()`.

Return Values:

Returns the type field of the message that caused `trigger_on_message()` to return.

See Also:

`init_trigger()`

Example:

```
#include <message.include>
#define The_sun_sets_in_the_west 1

main()
{
   MESSAGE message;
   int number_set;

   number_set = init_trigger(DATACOMM, 2 , DTE_FRAME, END_OF_DISC_RUN);
   printf("There are %d subtypes set by init_trigger for DATACOMM events.\n",
                                                                  number_set);
   number_set = init_trigger(TIMER, 32);
   printf("There are %d subtypes set by init_trigger for timer messages.\n",number_set);
   set_timer(10L);  /* timeout after 1 second */
   start_data(); /* start receiving DATACOMM events */

   while(The_sun_sets_in_the_west)
      switch(trigger_on_message(&message))
      {
         case DATACOMM:
            printf("Process DATACOMM messages here.\n");
            break;
         case TIMER:
            printf("Process TIMER messages here.\n");
            break;
         default: /* must be an error subtype */
            printf("Process ERROR messages here.\n");
      }
   getch();
}
```

ungetc( )

Format:

```
#include <stdio.include>

void ungetc(ch, file)
int ch;
FILE *file;
```

Description:

Pushes a character (ch) back onto an input stream. The stream may be a file, or the standard input device, stdin.

Return Values:

None

See Also:

```
getc(), ungetch()
```

Example:

```
#include <stdio.include>

main()
{
   int ch = 0;

   printf("Enter a character from the keyboard:\n");
   ch = getc(stdin);
   ungetc(ch,stdin);
   putch(ch);
   getch();
}
```

ungetch( )

Format:

```
#include <conio.include>

int ungetch(ch)
int ch;
```

Description:

Places a keystroke (ch) back into the system queue to be read by getch().

Return Values:

SUCCESSFUL (0)   There is no error return code.

See Also:

getch(), ungetc()

Library Functions

ungetch( )

Example:

```
#include <conio.include>
main()
{
    int ch = 0, result;
    char *str;

    ungetch(CLEAR_DISPLAY);
    str = "dlrow olleh";
    while(*str)
        if((result = ungetch(*str)) != 0)
            printf("Error ungetting %c - returned %x.\n",*str++,result);
        else
            str++;
    while ( ch != CLEAR_DISPLAY )
    {
        ch = getch();
        putch(ch);
    }
    getch();
}
```

Library Functions

unlink( )

Format:

```
int unlink (file)
char *file;
```

Description:

Deletes the file specified by `file`. The `file` parameter must include the path as well as the file name and extension for the file to be deleted.

Return Values:

0	The specified file was deleted.
-1	The file does not exist or could not be deleted.

See Also:

open( )

Example:

```
#include <stdio.include>
#include <fcntl.include>

main()
{
    int fdesc;
    long seek_result, write_result;
    char instr[20];

    if((fdesc = open("file1.text",O_WRONLY)) == -1 )
        printf("Can't open file1.text.");
    else
    {
        if(write_result = write(fdesc,"hello world\n",12) != 12 )
        {
            printf("Write error detected.");
            close(fdesc);
        }
        else
        {
            close(fdesc);
            if(unlink("file1.text"))
                printf("Error deleting the file");
            else
                printf("File has been deleted.\n");
        }
    }
    getch();
}
```

wait( )

Format:

```
int wait(number_of_tenths)
unsigned long number_of_tenths;
```

Description:

Blocks the calling process for the specified amount of time (measured in tenths of seconds).

Return Values:

`SUCCESSFUL (0)` There is no error return code.

See Also:

```
clear_timer(), set_timer()
```

Library Functions

Example:

```
main()
{
   printf("Press a key....\n");
   getch();
   printf("Going to wait for 5 seconds...\n");
   print_time();

   wait(50l);
   print_time();
   printf("Finished waiting...\n");
   getch();
}

#include "time.include"
print_time()
{
   struct tm time;

   get_time(&time);
   printf("The time is %d:%d:%d.%d\n",
         time.tm_hour,
         time.tm_min,
         time.tm_sec,
         time.tm_msecs );
}
```

wait_data()

Format:

```
int wait_data(data_type, timeout, data_event)
int data_type;
long int timeout;
MESSAGE *data_event;
```

Description:

Gets the first message of type DATACOMM and subtype data_type in the message queue and places the message into the buffer pointed to by data_event. If no message is immediately available, the function waits timeout milliseconds for another one.

Return Values:

SUCCESSFUL (0)	A DATACOMM message was received.
WARNING_1 (1)	The message was not a DATACOMM message.
WARNING_2 (2)	The DATACOMM message's subtype was not the same as specified in data_type.
ERROR_1 (-1)	There wasn't any message in the queue.

Library Functions

Example:

```
#include <message.include>
#include <retval.include>

main()
{
   MESSAGE message;
   char *frame_type[2];
   FRAME_EVENT *frame_ptr;
   int result;
   frame_type[0] = "DTE frame";
   frame_type[1] = "DCE frame";

   if((result = start_data()) != SUCCESSFUL)
   {
      printf("Data Transmit/Receive cannot be started - error # %d.",result);
      exit();
   }
   while(1)
   {
      switch(result = wait_data(DTE_FRAME,50L,&message))
      {
         case SUCCESSFUL:
            frame_ptr = message.body.event.event_ptr;
            printf("The following frame has been received:\n");
            printf("The frame's fcs is: %d.\n",frame_ptr->fcs);
            printf("The frame's type is: %d = %s.\n",
                  message.subtype,frame_type[message.subtype-1]);
            printf("The frame's length is: %d.\n",frame_ptr->length);
            printf("The frame's data starts at address: %lx.\n",frame_ptr->frame);
            release_event(message.body.event.event_ptr);
            break;
         case WARNING_1:
            printf("The message was not a a Datacomm message.\n");
            release_event(message.body.event.event_ptr);
            break;
```

Library Functions

wait_data()

```
            case WARNING_2:
                printf("The datacomm message was not a frame event.\n");
                release_event(message.body.event.event_ptr);
                break;
            case ERROR_1:
                printf("There is no message in the datacomm queue.\n");
                break;
            default:
                printf("Error code returned from wait_data is %d.\n",result);
                break;
        }
        getch();
    }
}
```

wait_lead()

Format:

```
#include <leads.include>

int wait_lead(lead_id, lead_state, timeout, lead_event);
long lead_id;
int lead_state;
unsigned long timeout;
MESSAGE *lead_event;
```

Description:

Scans the message queue and collects the first message of type `DATACOMM` and subtype `LEAD_CHANGE` with `lead_id` and `lead_state` as specified in the parameter list. When the desired message is found, the message is copied to the buffer pointed to by `lead_event`. If such a message cannot not found, the function waits for the duration of `timeout` (measured in milliseconds) before exiting.

`DATACOMM` messages that do not contain the correct lead id and state are automatically released through `release_event()`.

Like `set_lead()` and `get_lead()`, `wait_lead()` uses the file `leads.include` to define valid lead names and states. Recognized lead states are `ON`, `OFF`, and `DONT_CARE`; Valid lead names are shown on the next page:

Library Functions

wait_lead()

RS232C/MIL188C lead	RS232C/MIL188C clock & data	RS449 lead	RS449 clock & data	V.35 lead	V.35 clock & data
RTS	DTE_LEAD	RS	DTE_LEAD	RS	DTE_LEAD
CTS	DCE_LEAD	CS	DCE_LEAD	CS	DCE_LEAD
DSR	ETC	DM	TT	DSR	SCE
DTR	TC	TR	ST	DTR	SCT
RI	RC	IC	RT	RI	SCR

SQ	SRX	SQ	SRD	LT	
DRS		SI			
SRS		SRS			
SCS		SCS			
SCD		SRR			
		IS			
		SF			
		RL			
		SS			

Return Values:

SUCCESSFUL (0)

ERROR_2 (-2) The lead_state parameter was invalid.

ERROR_5 (-5) The timeout occurred before desired event was found. The lead_event parameter is set to NULL.

ERROR_6 (-6) System timers could not be set.

See Also:

get_lead(), set_lead()

Example:

```
#include <message.include>
#include <leads.include>
#include <dlib.include>
#include <retval.include>

main()
{
    MESSAGE message;
    if(start_data())
    {
        printf("Data Transmit/Receive cannot be started - error # %d.",result);
        exit();
    }
    while(1)
    {
        switch(wait_lead(DTR,OFF,50L,&message))
        {
            case SUCCESSFUL:

                break;
            case ERROR_5:
                printf("Timeout occurred before the desired event was found.\n");
                break;
            case ERROR_6:
                printf("Unable to set the system timers.\n");
                break;
        }
    getch();
    }
}
```

wipe( )

Format:

```
void wipe(row1, row2)
int row1, row2;
```

Description:

Clears the screen from `row1` to `row2`.

Return Values:

None

See Also:

```
write_vidram()
```

Example:

```
main()
{
    int i;

    set_rows(5, 15);
    for(i = 1; i < 30; i++)
        printf("This is row %d\n", i);
    printf("Press any key to clear the screen");
    getch();
    wipe(5,20);
    printf("Press any key to exit");
    getch();
}
```

Library Functions

write( )

Format:

```
#include <stdio.include>

int write(fdesc, buff, cnt)
int fdesc;
char buff[];
unsigned int cnt;
```

Description:

Writes `cnt` bytes from the storage buffer `buff[]`, to the file whose descriptor is `fdesc`. The `fdesc` parameter contains an integer that was generated by the `open` function when the file was first encountered in the program. The number of bytes transferred cannot exceed 64K.

Return Values:

Returns the number of bytes actually written, which may be less than `cnt` if the function runs out of disc or file space before `cnt` bytes are written.

See Also:

`open(), read()`

write( )

Example:

```
#include <stdio.include>
#include <fcntl.include>

main()
{
    int fdesc;
    long seek_result, write_result;
    char instr[20];

    printf("The string \"hello world\" will be written to file1.text.\n");
    if((fdesc = open("file1.text",O_WRONLY|O_CREAT)) == -1)
        printf("Can't create file1.text.");
    else
    {
        if(write_result = write(fdesc,"hello world\n",12) != 12)
            printf("Write error detected.");
        close(fdesc);
    }
    getch();
}
```

write_rs232()

Format:

```
void write_rs232(ch)
char ch;
```

Description:

Writes the character ch to the RS232 port.

This function must not be used until `init_rs232()` has been called.

Return Values:

None

See Also:

`init_rs232(), rs232_read_ready(), rs232_write_ready(), print_char(), read_rs232()`

write_rs232()

Example:

```
#include <conio.include>

/* A Dumb terminal emulator, terminates after the '~' character is typed */
/* on the keyboard....                                                 */

main()
{
    char ch = 0;

    init_rs232();

    printf("Terminal Emulator - press \"~\" to exit.");
    while(ch != '~' )
    {
        if(is_key_avail())
        {
            ch = getch();
            while (!rs232_write_ready()) ;
                write_rs232(ch);
        }
        if(rs232_read_ready())
        {
            read_rs232(&ch);
            putch(ch);
            ch = 0;
        }
    }
}
```

write_vidram( )

Format:

```
#include <video.include>

void write_vidram(row, column, character, attribute)
int row, column;
int attribute;
char character;
```

Description:

Writes `character` and its `attribute` to the video RAM location indicated by `row` and `column`. The formatted character appears on the display in the position `row, column`. This function is not affected by the text window areas created by set_rows(), and allows text and messages to be printed to any area of the display.

This function has no effect on the current cursor position.

Return Values:

None

See Also:

```
read_vidram()
```

write_vidram()

Example:

```
#include <video.include>

main()
{
    char ch;
    int row = 1, col = 1;
    int attribute;
    char *outstr;

    outstr = "1234567890123456789012345";
    for(;row <= 25;row++,col++)
        if(row & 0x0001)
            write_vidram(row,col,*outstr++,NORMAL);
        else
            write_vidram(row,col,*outstr++,BLINK);
    getch();
}
```

Include Files

The files listed in this chapter are located in the c:C/Include directory. Include files are stored as text, so they can be edited or printed through the Development Environment. Figure 4-1 shows a list of the include files in this chapter:

ascii.include	message.include
assert.include	retval.include
conio.include	setjmp.include
ctype.include	stdio.include
decode.include	stdlib.include
dlib.include	string.include
ebcdic.include	system.include
fcntl.include	time.include
leads.include	video.include
math.include	

Figure 4-1. Include files in the c:C/Include directory

When used in source code, the include file names must be entered as lowercase letters, but the .include extension may be replaced by .h; for example, the line "#include leads.include" may be represented by "#include leads.h" in a .csource file.

Include Files

ascii.include

This include file contains ASCII values for data codes.

```
#define as_NUL          0
#define as_SOH          1
#define as_STX          2
#define as_ETX          3
#define as_EOT          4
#define as_ENQ          5
#define as_ACK          6
#define as_BEL          7
#define as_BS           8
#define as_HT           9
#define as_LF           10
#define as_VT           11
#define as_FF           12
#define as_CR           13
#define as_SO           14
#define as_SI           15
#define as_DLE          16
#define as_DC1          17
#define as_DC2          18
#define as_DC3          19
#define as_DC4          20
#define as_NAK          21
#define as_SYN          22

```

setjmp.include

This include file defines values for `setjmp()` and `longjmp()`.

```
#define   JBUFSIZE  14

typedef long jmp_buf[JBUFSIZE];
```

stdio.include

This include file defines standard I/O values and macros, and data structures for accessing disc files.

```
#ifndef _STDIO_H
#define _STDIO_H
#define fgetc getc
#define fputc putc

#ifndef NULL
#define NULL                    0L
#endif

#define EOF                     -1

#define TRUE                     1
#define FALSE                    0

#define STDINSIZE               80

#define SEEK_END                    2
```

stdlib.include

This include file contains function definitions for the standard library.

```
double atof();
int  atoi();
long atol();
char *calloc();
void free();
char *itoa();
char *ltoa();
char *ftoa();
char *malloc();
```

string.include

This include file contains declarations for string manipulation functions.

```
char *strcat();
char *strchr();
char *strcpy();
char *strncat();
char *strncpy();
char *strrchr();
char *strsave();
char *strstr();
char *strtrm();
```

system.include

This include file defines values for system (PSOS) status and error codes.

```
#define DEFAULT_PRIORITY                100

/* Spawn error codes           */
#define CANT_OPEN_PROGRAM_FILE           -1

            _code_segment;  /*beginning of process code segment */
```

time.include

This include file defines the data structure used in the real-time clock access functions.

```
/* tm structure used by get_time() and set_time() */
struct tm
   {
   int tm_msecs;
   int tm_sec;
   int tm_min;
   int tm_hour;
   int tm_day;
   int tm_mon;
   int tm_year;
   };
```

video.include

This include file contains values for the video I/O functions.

```
/*** constants used by set_attribute() and get_attribute() ***/

/* ASCII character attributes */
#define NORMAL                  0x0200
#define INVERSE                 0x0600

Include Files

A

Video Character Sets

The DataCommC Programming Language gives you access to the HP 4954A Protocol Analyzer's ASCII, Hex and EBCDIC video character sets, as well as four additional display banks that include graphics and Katakana characters. The character sets may be selected with the `set_attribute` function, and if the `SPECIAL` attribute is chosen, one of the four graphics display banks may be selected using `set_disp_bank()`.

The individual characters contained in the character sets and display banks are shown in the tables on the following pages.

Graphics Display Characters
